

2026 TWG Quarterly Meeting

Quantify the Real Impact of Transportation Activity on Regional Ozone

Sponsored by the
Texas Department of Transportation

Bumsik Kim, Ph.D. (b-kim@tti.tamu.edu)
Program Manager
Environmental Modeling Program
Texas A&M Transportation Institute
March 5, 2026

Table of Contents

- Project Overview
- Transportation Activity and Emission Modeling
- Regional Photochemical O₃ Modeling
- Conclusions

Project Overview

Project Overview

- Background

TxDOT, TCEQ, and MPOs rely on modeling to comply with air quality regulations

Currently accepted assumption:

Reduced emission from traffic automatically means improved air quality

Air quality data observed during the pandemic showed mixed behavior

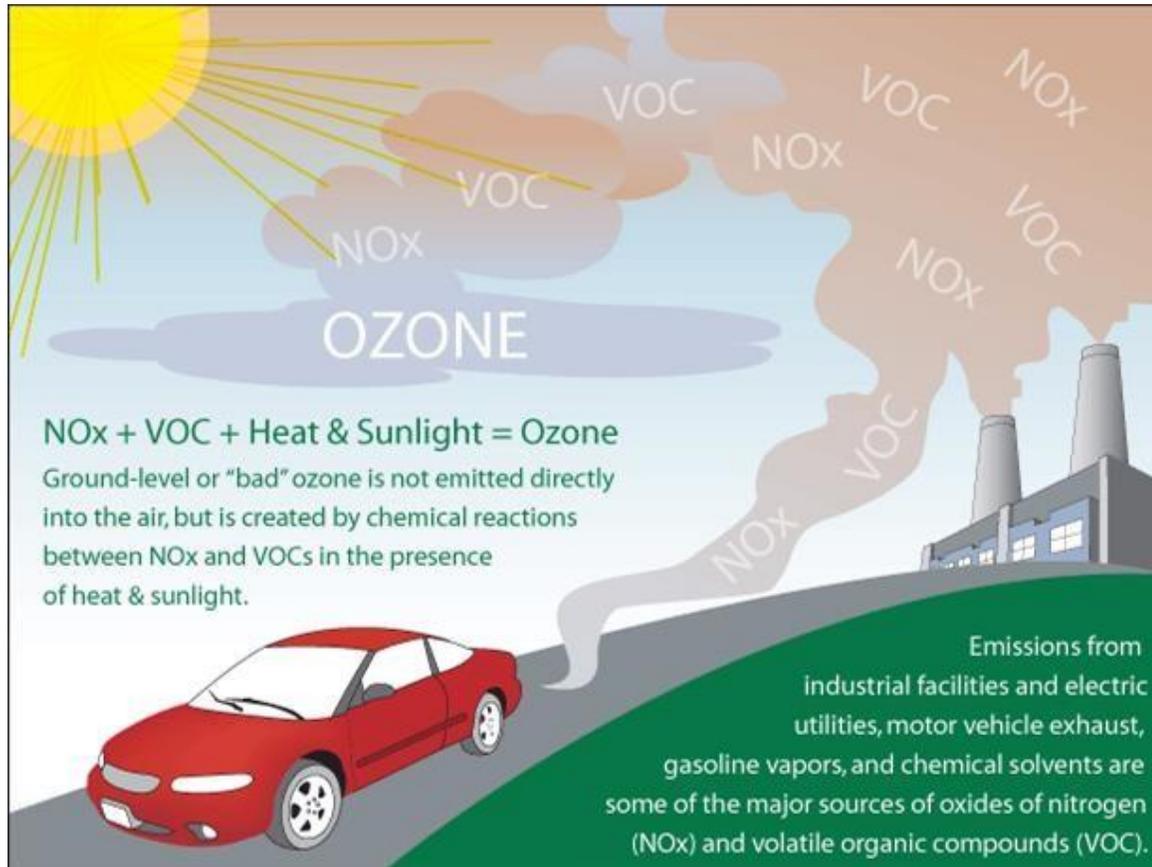

Pandemic-induced changes in transportation activities created an opportunity to examine the details of the impact of traffic-related emissions on air quality

Project Overview

- Quantify the Real Impact of Transportation Activity on Regional Ozone and Near-Road PM Concentrations
 - Examine the **extent of transportation's impacts on air quality** through an analysis of **before-** and **during-pandemic** traffic activity and air quality monitoring data
 - **Evaluate the performance** of
 - **Photochemical modeling** in capturing the changes in **regional O₃** in response to changes in traffic activities
 - **Air dispersion modeling** in capturing the changes of **near-road PM_{2.5}** concentrations in the near-road environment resulting from traffic activity variations

Why ground-level O₃?

- Ground-level O₃ forming process

- O₃ is the main ingredient of Smog

- PBS documentary film "Clearing the Air: the War on Smog" [Link](#)

Transportation Activity and Emission Modeling

Transportation Activity and Emission Modeling

- Assumption

- Core assumptions of the study
 - COVID-19 **changes individual travel behavior**
 - COVID-19 **changes population** in a region
 - Use **different factors (variables)** for **COVID** and **No COVID scenarios** if data can support the assumption. In other words, **use the same factors** for COVID and No COVID **if there is no evidence/data** to show the differences.

Transportation Activity and Emission Modeling

- Scope of the Study

- Temporal scope

- Split year 2020 into four, based on business restriction executive order due to COVID-19

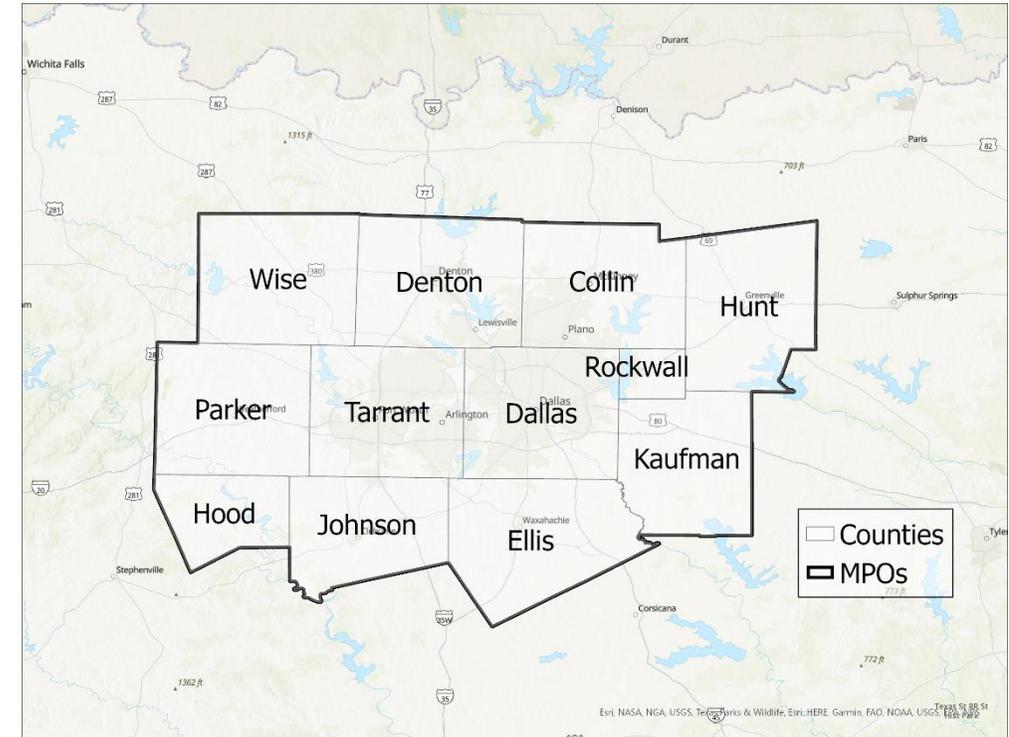

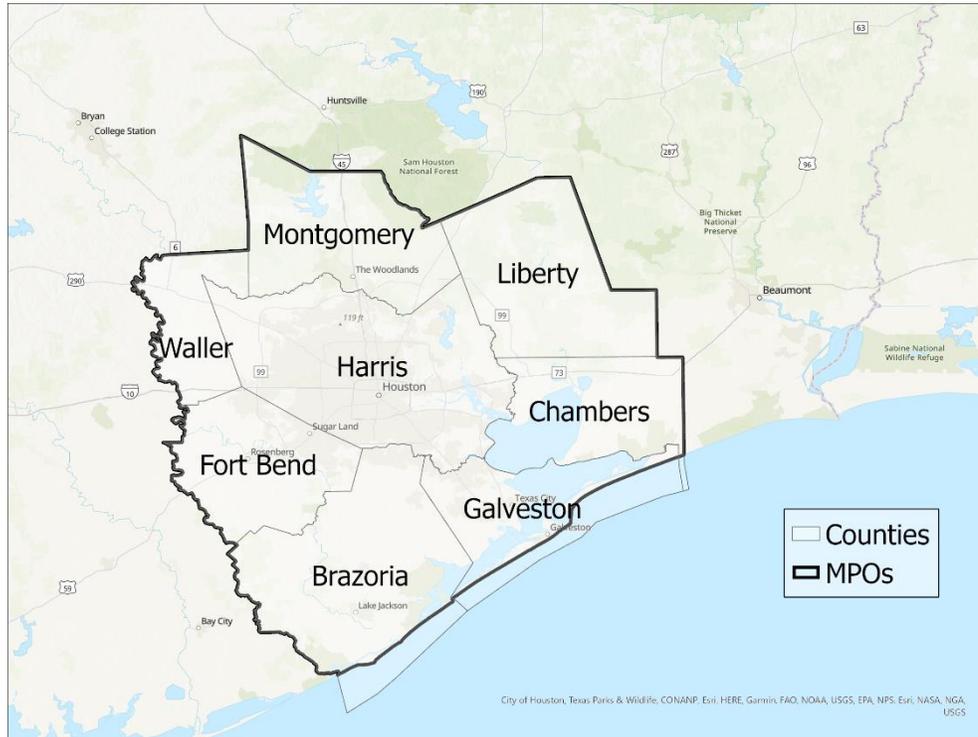

- Before lockdown (P1) : Before significant COVID-19 impact, no stay-at-home order
- Lockdown Phase I (P2) : Execute stay-at-home order
- Lockdown Phase II (P3) : Open business at 25% capacity → 75% capacity
- After lockdown (P4) : End of O₃ season

Transportation Activity and Emission Modeling

- Scope of the Study

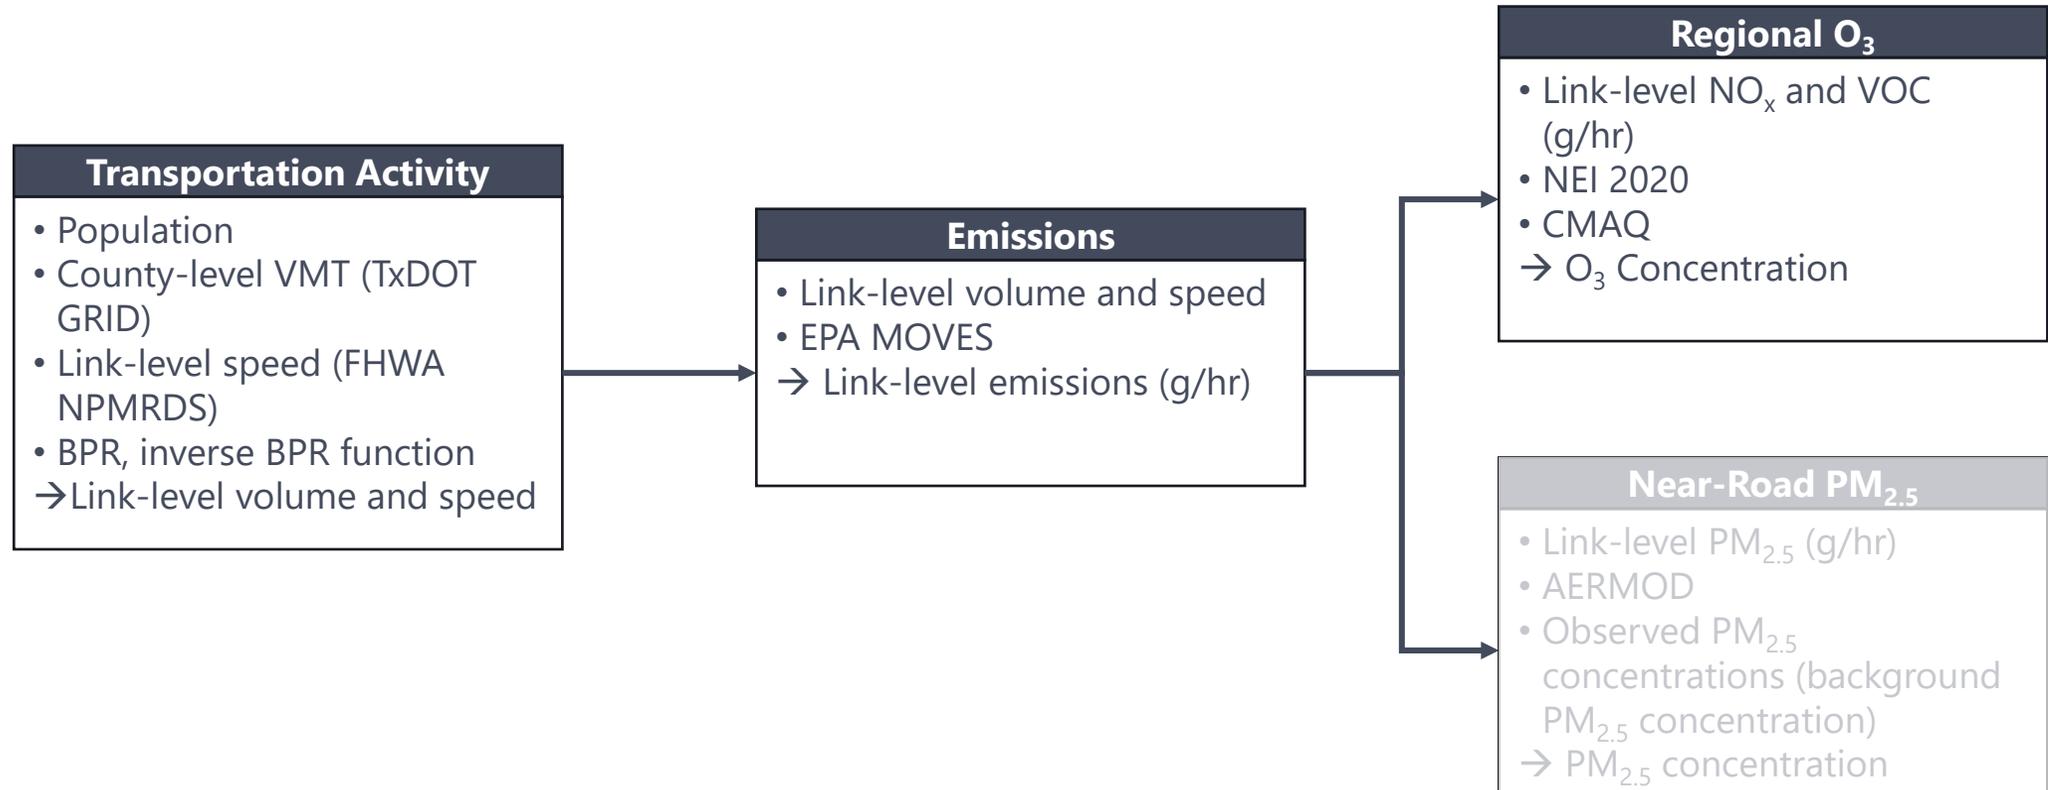

- Spatial scope for regional O₃
 - Houston (HGB) and Dallas Fort Worth (DFW)—two O₃ nonattainment areas in Texas

Transportation Activity and Emission Modeling

- Modeling Chain in this study

- Emission concentration modeling chain (full modeling chain)

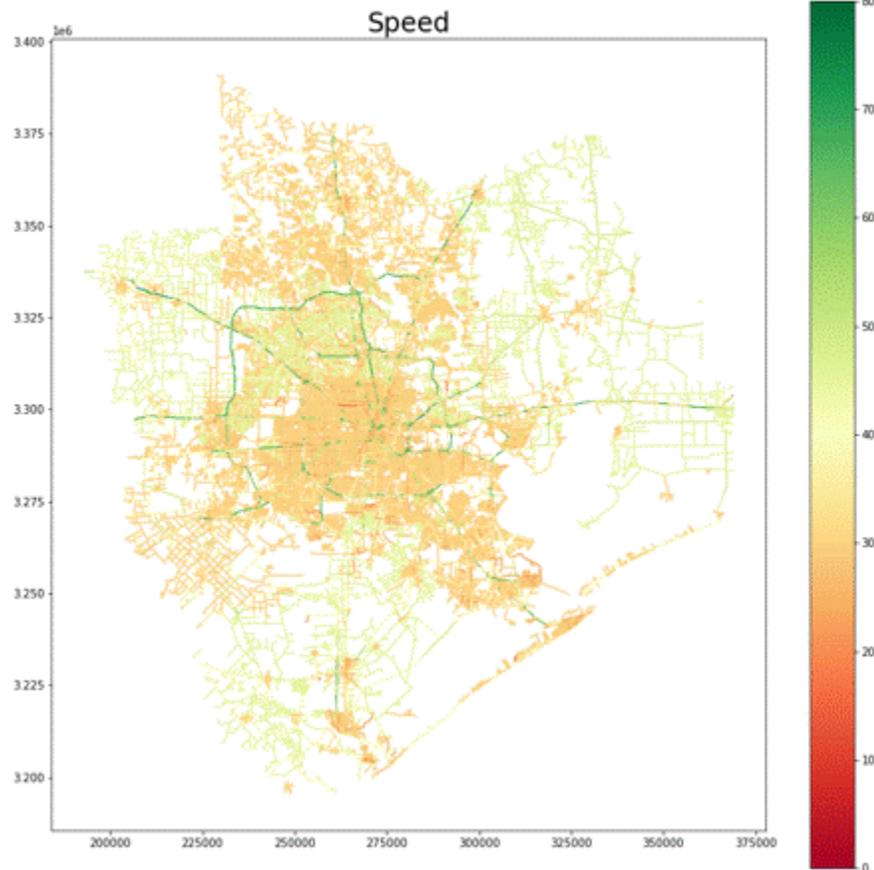

Transportation Activity and Emission Modeling

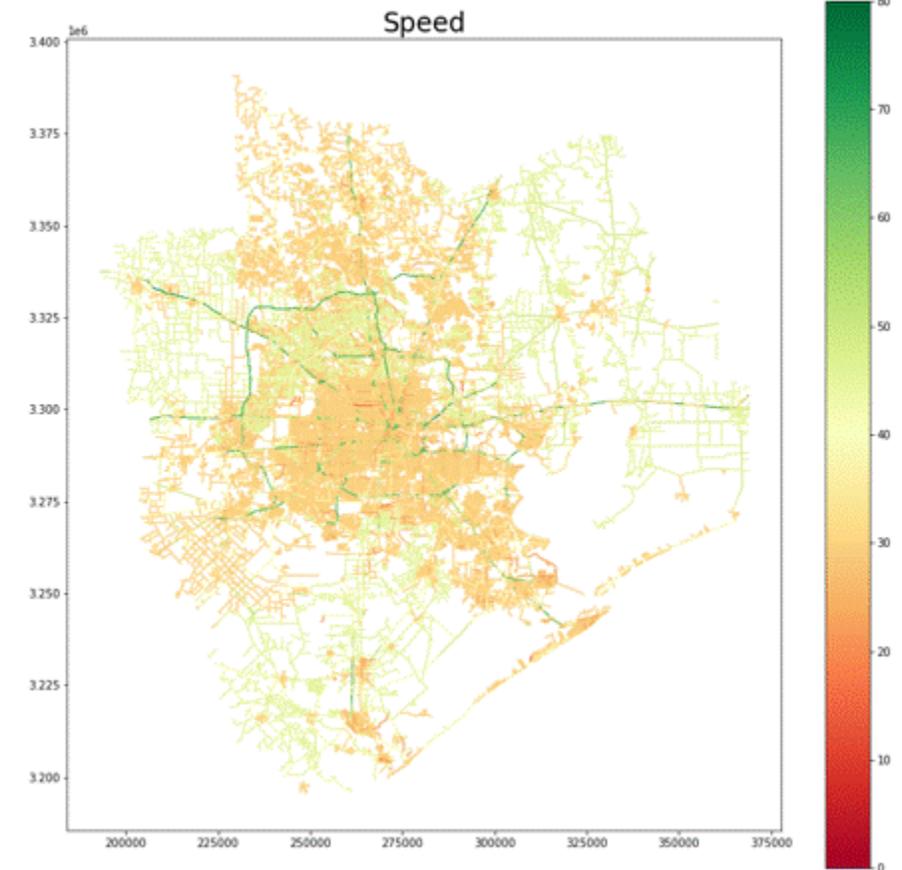

- Estimating Transportation Activities

- Transportation activities output
 - Speed comparison: COVID vs. No COVID, lockdown Phase I (P2)

2020 COVID Scenario, P2 Weekday at 0

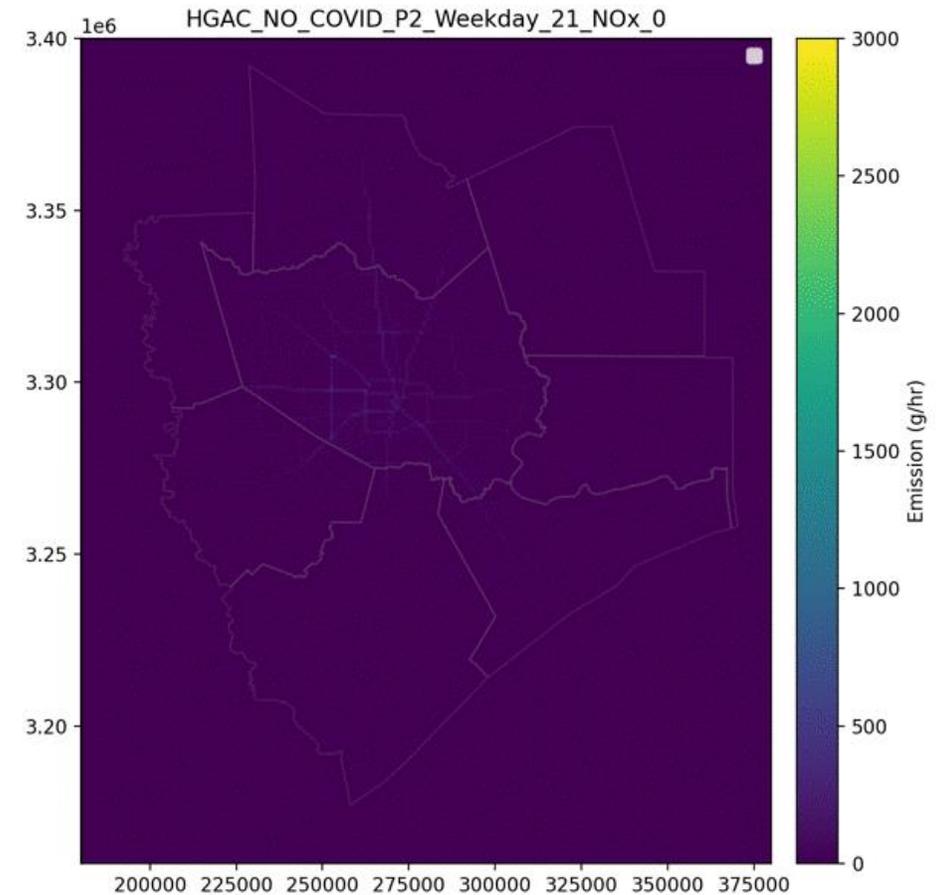

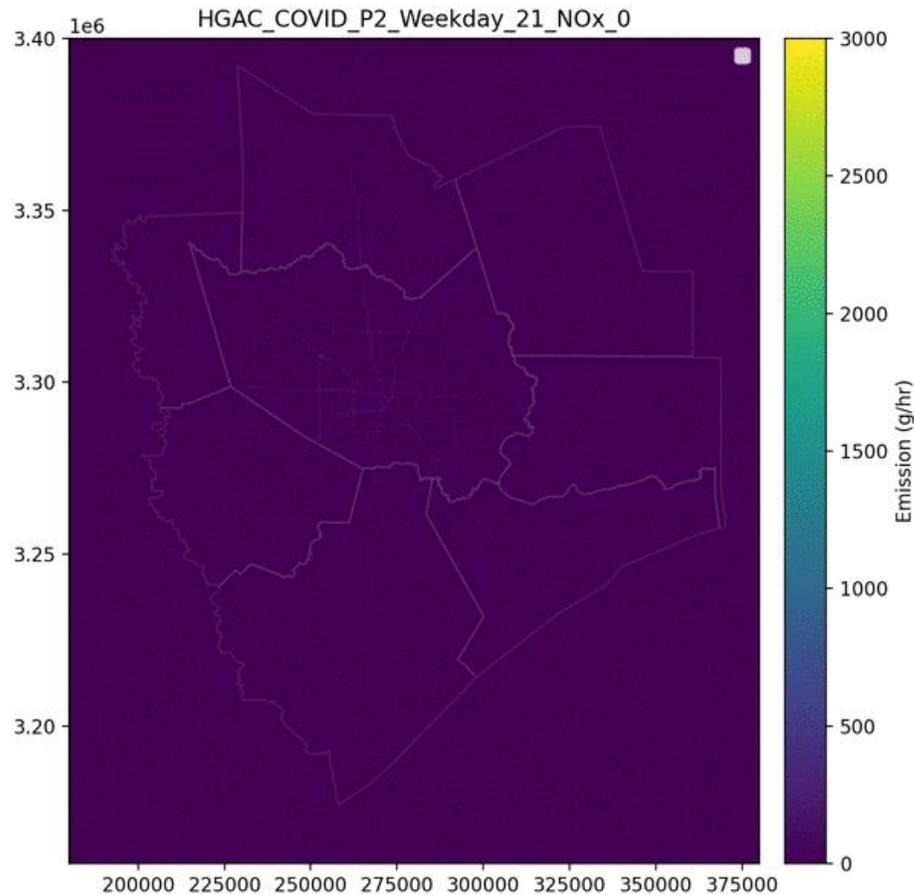

2020 NO COVID Scenario, P2 Weekday at 0

Transportation Activity and Emission Modeling

- Estimating Emissions

- Emission Estimation (MOVES3)
 - NO_x (g/hr) comparison: COVID vs. No COVID, lockdown Phase I (P2)

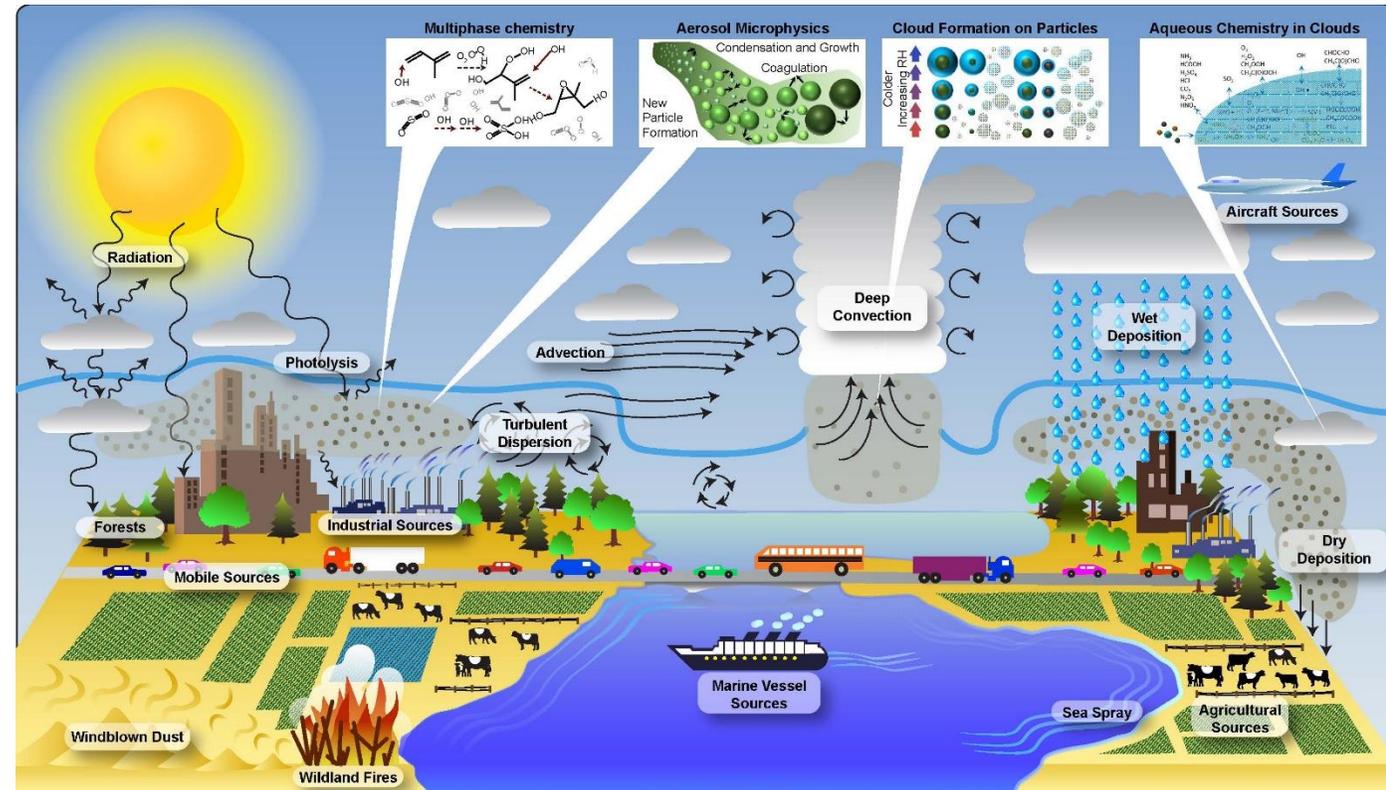

Regional Photochemical O₃ Modeling

Regional Photochemical O₃ Modeling

- Atmospheric Models Are Essential Tools

- Numerical modeling is required because:
 - Pollutants of concern are not always directly emitted but often created in the atmosphere
 - Atmospheric chemistry is complex and nonlinear
- Atmospheric models allow us to:
 - Simulate the complexity of atmospheric chemistry
 - Understand future air quality
 - Fill in gaps spatially where monitors do not exist
 - Formulate and test potential control strategies

Source: U.S. EPA

Regional Photochemical O₃ Modeling

- Community Multiscale Air Quality (CMAQ) Modeling System

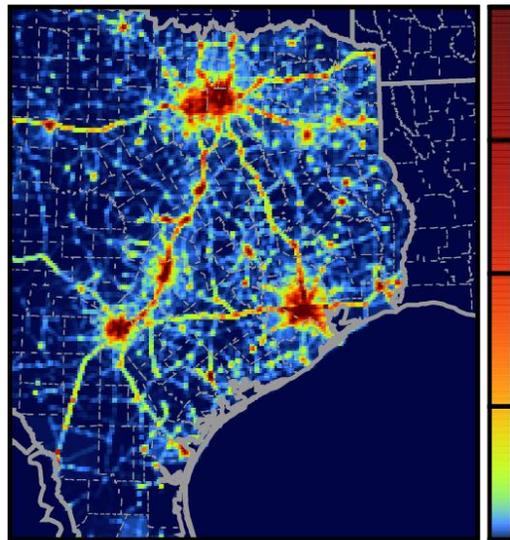

TAMU High Performance Research Computing

CMAQ predicts hourly concentration and deposition values for a large number of chemical species for each location in the modeled domain

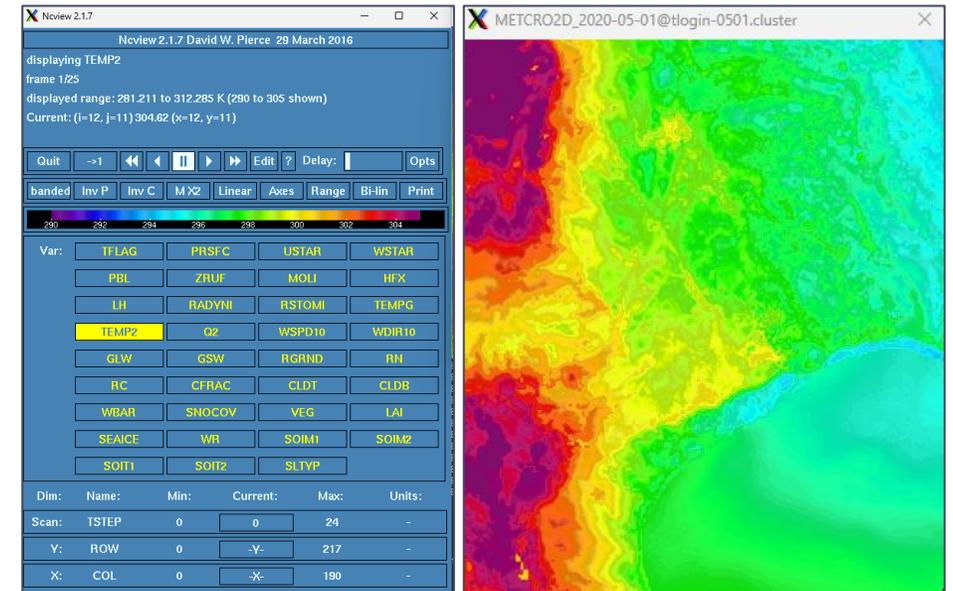

Key Inputs

- 2020 National Emission Inventory (NEI)
- Weather Research and Forecasting (WRF)
- Estimated on-road emission (previous step)

NEI NO_x Emission (Ton)

20
15
10
5

WRF Predicted 2m Temperature (K)

Regional Photochemical O₃ Modeling

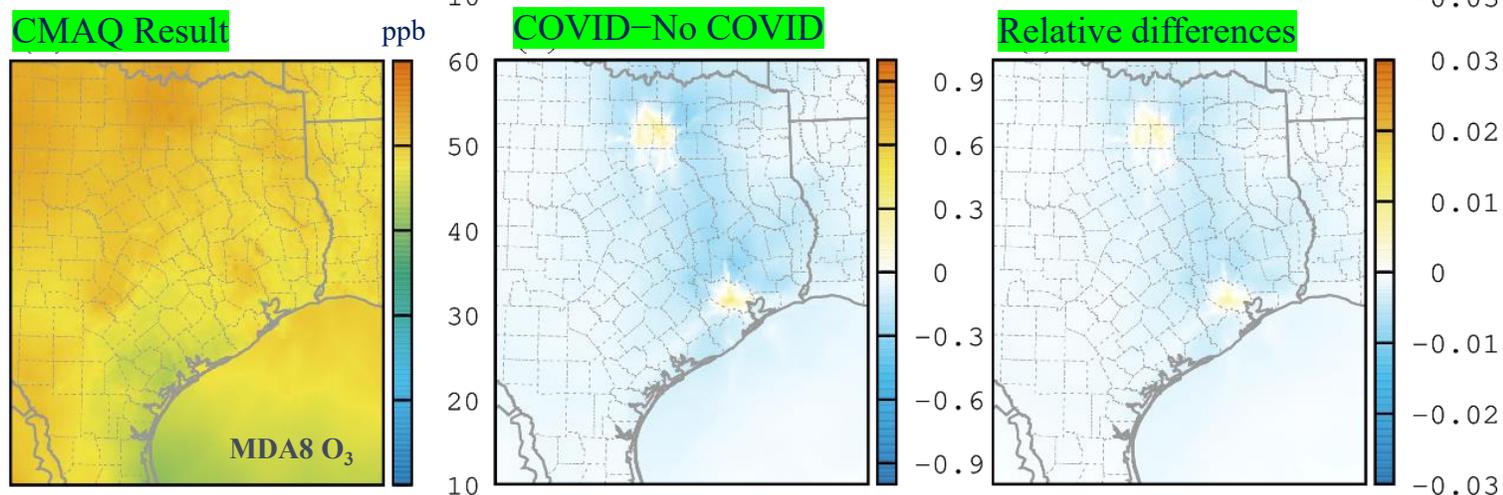

- Model Results

- MDA8 O₃ differences (COVID v. No COVID) in P2

Mar 15 – Mar 31

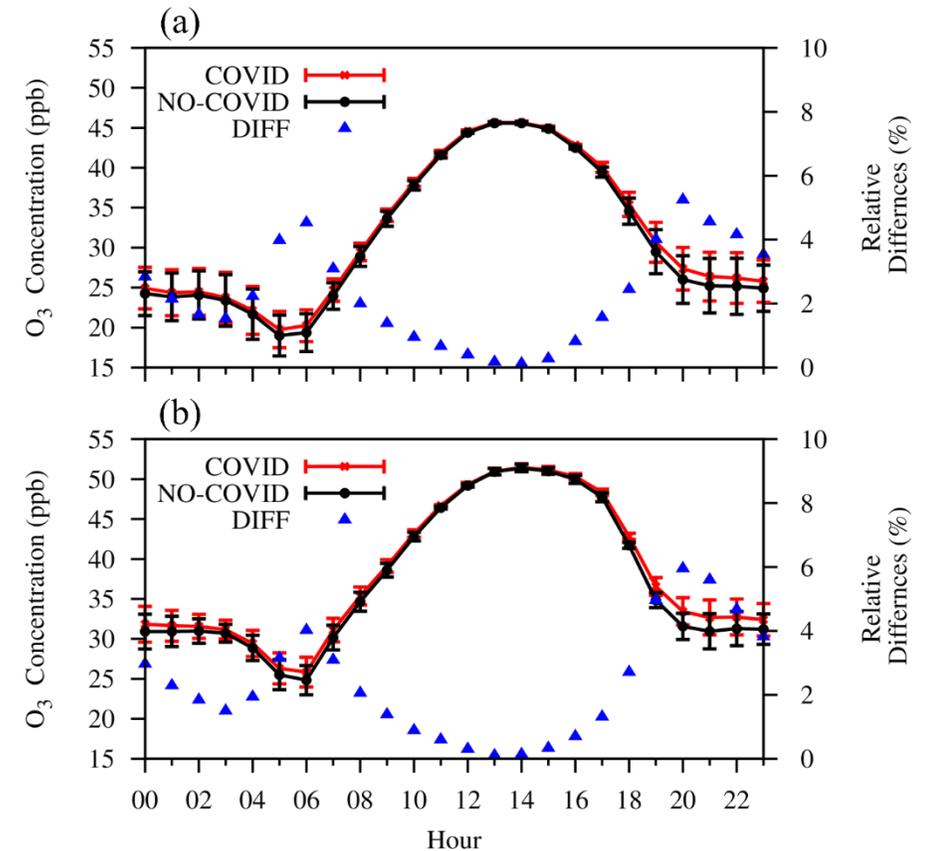

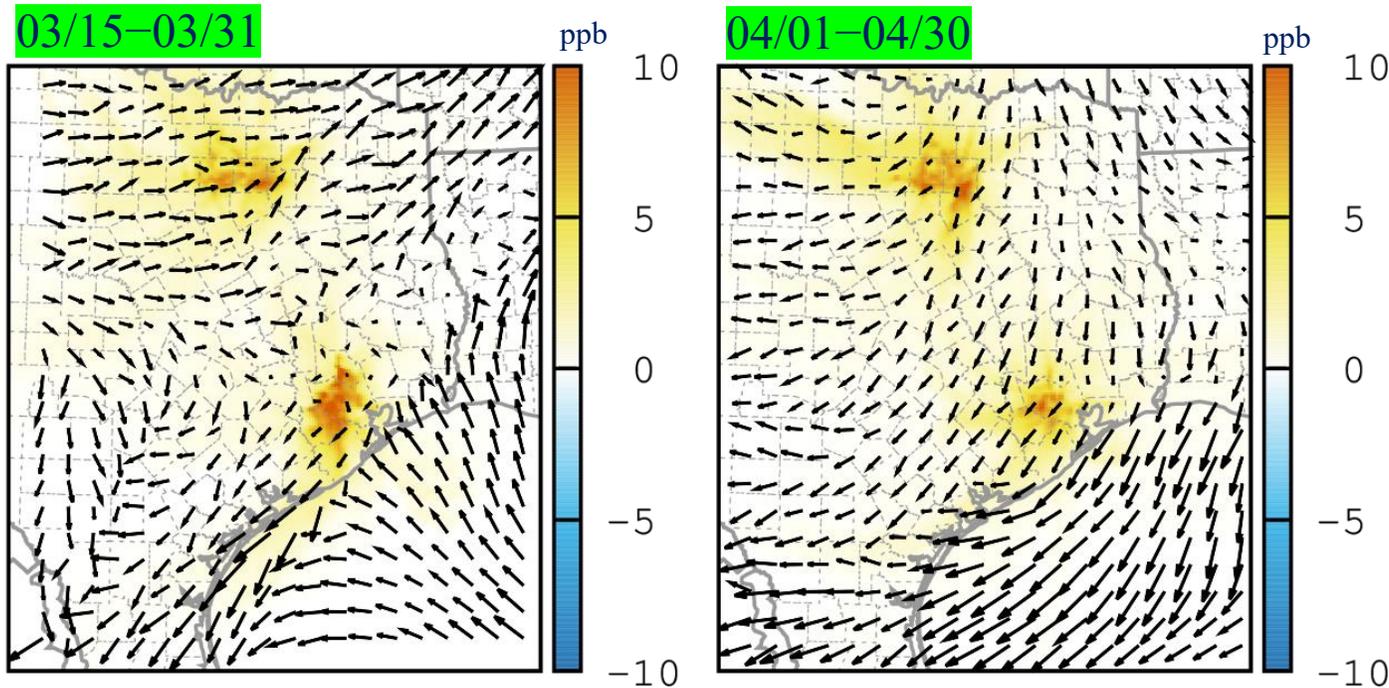

Apr 1 – Apr 30

Regional Photochemical O₃ Modeling

- Model Results

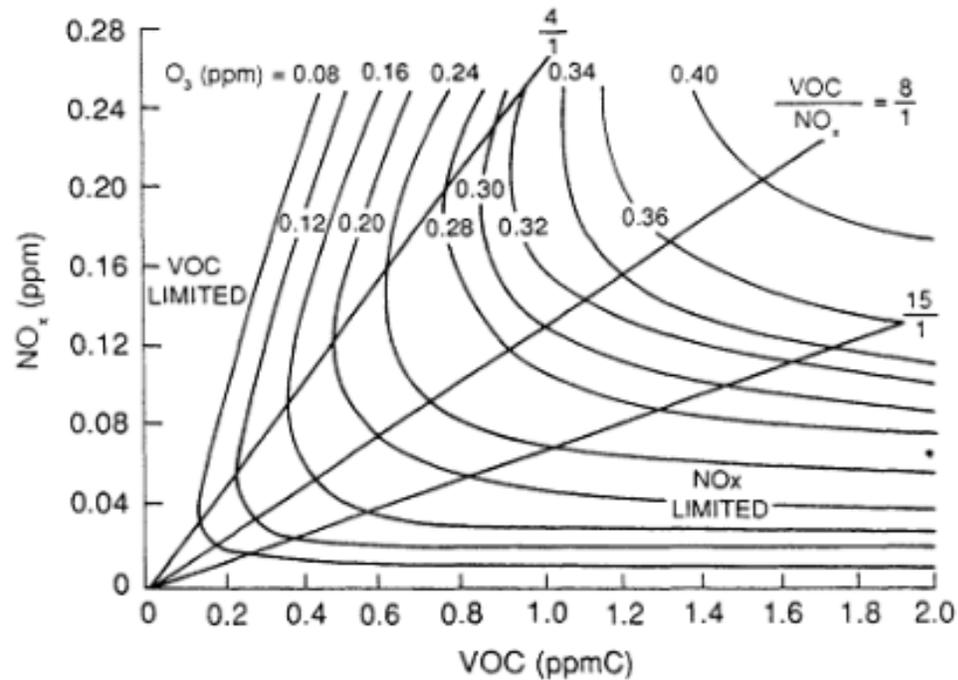

- Hourly O₃ differences (COVID v. No COVID) in P2
 - Significant O₃ reduction during the night/early morning (see ▲)

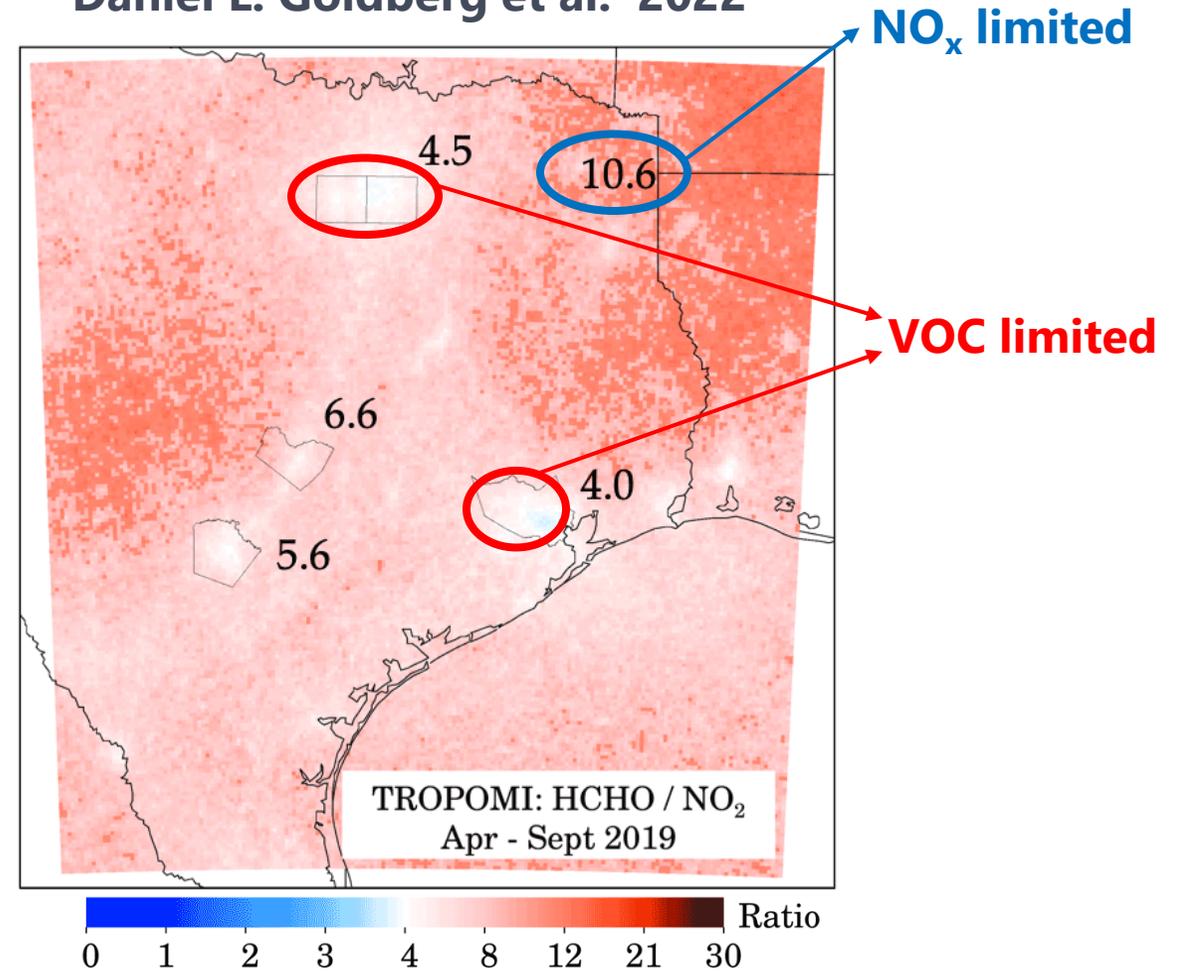

Regional Photochemical O₃ Modeling

- Ozone Formation

Finlayson-Pitts and Pitts et al. 1993

Daniel L. Goldberg et al. 2022

NO_x limited = with relatively low NO_x and high VOCs
VOC limited = with relatively high NO_x and low VOCs

Regional Photochemical O₃ Modeling

- Ozone Formation

- Urban areas in Texas are **VOC-limited** regime (more NO_x, less VOC)
 - More **NO_x cannot generate** more O₃
 - More **VOC can generate** more O₃
- O₃ titration can reduce O₃ during the nighttime
 - O₃ is generated by NO_x, VOC, Heat, and sunlight (balance matters)
 - During the nighttime, when the heat and sunlight are limited, O₃ is depleted through its reaction with NO, leading to the removal of O₃

- Since our target areas are VOC-limited (plenty of NO_x, including NO), O₃ was reduced (especially when there is no heat and sun) due to the O₃ titration

Conclusions

Conclusions

- Two major factors that affect transportation activity changes due to COVID-19
 - Individual travel behavior: people travel less (lockdown, WFH, etc.)
 - Population change: migration from other states, moving out to the suburbs
- During COVID, Urban areas experienced less than a 1.5 ppb increase in maximum daily 8-hour average (MDA8) O₃ due to the reduced O₃ titration effect (VOC-limited regime)
- Suburban/rural areas had a slight decrease in MDA8 O₃ (NO_x-limited regime) in the COVID scenario compared to the No COVID scenario

Takeaways – What does the result mean?

- Texas currently has several metropolitan areas that are regulated under the Clean Air Act, and the state is generally interested in **reducing the impacts of transportation on the environment**
- Modeling transportation activities, emissions, and air quality (i.e., pollutant concentrations) is required for regulatory decision making → **Full modeling chain (transportation → emission → concentration) is needed**
- The results of this study suggest that established modeling methodologies are useful tools for predicting and **understanding the contribution of historical transportation activities to air quality**
