

Barnegat Bay Environmental Educators Roundtable, April 27, 2022
Ocean County Soil Conservation District
Soil Science Sampler Activity Packet

Soil Texture:

Soil texture refers to the sand, silt and clay sized particles that make-up the mineral fraction of soil. Soil texture determines the amount of water a soil can hold, the rate of water movement through the soil, the structure of a soil, and texture contributes to a soil's fertility. For example, sandy soil is well aerated, but does not hold water or nutrients. Clay soils generally hold more water and nutrients but can be susceptible to compaction, which reduces air space and limits the ability of soil organisms to function properly.

Soil texture is determined by the percentages of grain size, **sand**, **silt** and **clay**, present in a soil. Classification names shown in the table below typically refer to the primary constituent particle size, or a combination of the most abundant particle sizes (e.g. "sandy clay" or "silty clay"). A fourth term, "loam" is used to describe a roughly equal concentration of sand, silt, and clay, and lends to the naming of even more classifications (e.g. "clay loam" or "silty loam" or "sandy clay loam").

The 3 soil texture classes: sand, silt and clay, are divided into 12 soil texture subclasses, defined by the USDA:

Sand	Silt	Clay	Loam
Loamy Sand		Sandy Clay	Sandy Loam
		Silty Clay	Silty Loam
			Clay Loam
			Sandy Clay Loam
			Silty Clay Loam

Sand (2.0mm – 0.05mm)

Silt (0.05mm-0.002mm)

Clay (less than 0.002mm)

Soil Texture Triangle:

Determining soil texture of a soil sample is often aided with the use of a **soil texture triangle** (a ternary diagram is a 3-sided diagram, or a diagram with 3 axes, or a diagram with 3 parts) containing the following percentages of sand, silt and clay.

Examples:

Sand: 40% Silt: 40% Clay: 20% = loam
Sand: 60% Silt: 15% Clay: 25% = sandy clay loam
Sand: 10% Silt: 45% Clay: 45% = silty clay

Complete the following:

1. Sand: 33% Silt: 33% Clay: 34% = _____
2. Sand: 50% Silt: 10% Clay: 40% = _____
3. Sand: 80% Silt: 5% Clay: 15% = _____

Activity #1: Ribbon Test:

You can estimate the texture of your soil by “feel”, by rubbing soil together between your finger and thumb. **Sand** has a loose, grainy feel and does not stick together. Individual sand grains can be seen with the naked eye. **Loams** are soft and will break into small pieces that stick together. When loamy soil is wet, it’s difficult to feel the sand grains. **Clays** exhibit a “plastic” behavior and can be molded when wet. When dry, clays become brittle and may crack. Perform the “Ribbon Test” to determine the texture of a soil sample by “feel”.

Activity #2: Jar Test

A “Jar Test” can provide an estimation of percentage of sand, silt and clay that are contained within a soil sample. Follow directions below and complete your measurements.

Helpful Resources:

- Understanding Soil Types and Texture (video)
<https://www.youtube.com/watch?v=AUhOBxVFcFk>
- Rutgers Soil Testing Lab – How to Collect a Soil Sample
<https://www.youtube.com/watch?v=32KqO4NWxo>

Fill a jar about $\frac{1}{4}$ to $\frac{1}{2}$ full with a soil sample. Fill the jar about $\frac{3}{4}$ full with water. Screw the lid on **tightly**, and shake. Let the sample jar sit for 24-48 hours to allow the particles to settle. The sand will settle first because the large sand particles do not hold a charge and do not react chemically with water. The silt particles stay suspended for 1-2 hours. The clay particles are very small and will stay suspended for up to 48 hours.

Once your soil sample settles, use a ruler to measure the layers in millimeters and convert the measurement to a percentage. Here is an example to show you how:

$$\text{Sand} + \text{Silt} + \text{Clay} = \text{Total}$$

$$30 + 22 + 25 = 77$$

$$\% \text{Sand} = 30/77 \times 100 = \mathbf{39\%}$$

$$\% \text{Silt} = 22/77 \times 100 = \mathbf{29\%}$$

$$\% \text{Clay} = 25/77 \times 100 = \mathbf{32\%}$$

In the above example, the sum of the 3 percentage values equals 100%. Use the soil texture triangle to determine the classification of the soil samples used in the Jar Test. Round to the nearest whole number.

Example:

Jar Test measurements:

$$\begin{array}{rcccccc} \underline{\text{Sand}} & + & \underline{\text{Silt}} & + & \underline{\text{Clay}} & = & \underline{\text{Total}} \\ 21 \text{ mm} & + & 10 \text{ mm} & + & 2 \text{ mm} & = & 33 \text{ mm} \end{array}$$

Convert to Percentage:

$$\% \text{Sand} = 21/33 \times 100 = 64\%$$

$$\% \text{Silt} = 10/33 \times 100 = 30\%$$

$$\% \text{Clay} = 2/33 \times 100 = 6\%$$

(Percentages should = 100%)

Soil texture class:

Use the soil texture triangle to determine what texture results in 64% sand, 30% silt and 6% clay. Answer: sandy loam

You Try!

Now, choose 3 jars and complete the measurements and calculations, then determine the soil classification based on your percentages.

1. Jar # _____

Jar Test measurements:

$$\underline{\text{Sand}} + \underline{\text{Silt}} + \underline{\text{Clay}} = \underline{\text{Total}}$$

$$\underline{\quad} + \underline{\quad} + \underline{\quad} = \underline{\quad}$$

Convert to Percentage:

$$\% \text{Sand} =$$

$$\% \text{Silt} =$$

$$\% \text{Clay} =$$

(Percentages should = 100%)

Soil texture class: _____

2. Jar # _____

Jar Test measurements:

$$\underline{\text{Sand}} + \underline{\text{Silt}} + \underline{\text{Clay}} = \underline{\text{Total}}$$

$$\underline{\quad} + \underline{\quad} + \underline{\quad} = \underline{\quad}$$

Convert to Percentage:

%Sand =

%Silt =

%Clay =

(Percentages should = 100%)

Soil texture class: _____

3. **Jar #** _____

Jar Test measurements:

Sand + Silt + Clay = Total

_____ + _____ + _____ = _____

Convert to Percentage:

%Sand =

%Silt =

%Clay =

(Percentages should = 100%)

Soil texture class: _____

Importance of Soil Texture (particle size) to Nutrient Holding Capacity:

When conducting the Jar test, you'll notice that the clay take a long time to settle out. Why? The clay takes a long time to settle out because the tiny clay particles hold negative charges (anions). When the tiny clay particles come close to each other they are repulsed, prohibiting them from joining together and forming heavier aggregates that settle to the bottom. It takes 24-48 hours for the clay particles to finally settle.

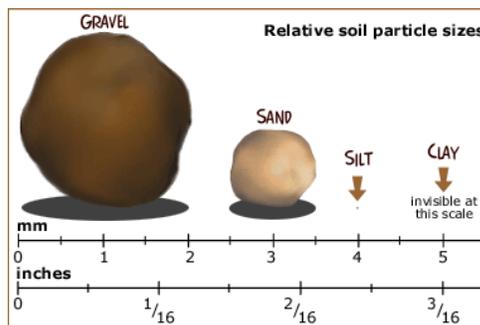

Clay particles are a chemically active portion of soil. Their negative charges, called **anions**, attract with positively charged **cations**. Many nutrients are cations. This property allows tiny clay particles (and tiny organic matter particles) to attract and hold onto nutrients in the soil that may otherwise be lost to leaching. This is why our sandy soils are poor in nutrients – because the large sand (and silt) particles do not hold a charge.

Activity #3: Soil Sieve Analysis

The Soil Sieve Analysis, also called Particle Size Analysis, is carried out with the utilization of a set of sieves with different mesh sizes. Each sieve mesh has square-shaped openings of a certain size. The sieve separates larger from smaller particles, distributing the soil sample. The grains with diameters larger than the size of the openings are retained by the sieve, while smaller diameter grains pass through the sieve.

This set of sieves provided will determine how much of your soil sample is **gravel** (gravel is not considered to be “soil”), how much is **coarse sand**, how much is **medium sand** and how much is **fine sand**, and the rest (very fine sand, silt and clay) will be captured together in the bottom pan.

Soil type	Particle Size (mm)	
Clay	<0.002	
Silt	0.002-0.075	
Sand	Fine	0.075-0.42
	Medium	0.42-2.0
	Coarse	2.0-4.75
Gravel	4.75-75	

The test is conducted by placing a series of sieves with progressively smaller mesh sizes on top of each other and passing the soil sample through the stacked sieve “tower”. Therefore, the soil particles are distributed as they are retained by the different sieves. A pan is also used to collect the smallest particles (very fine sand, silt and clay) that pass through the last sieve. Complete the Soil Sieve Analysis, then record your results in Chart B.

Helpful Resources:

- Particle Size Analysis (Sieves and Hydrometer) Missouri University (video) <https://www.youtube.com/watch?v=QqxfwpUtEoQ>
- Sieve Analysis https://www.youtube.com/watch?v=j5_6lXOwmv0

Procedure:

1. Record the weight of each of the sieves, as well as the bottom “pan”.
2. Stack the sieves in order with larger mesh on top (#6 on top, then #20, then #40, then #100 on bottom, then pan below #100).
3. Weigh a 100 gram dry soil sample.
4. Pour the soil sample into the top sieve and cover the stack with the cap.
5. Shake for 10 minutes.
6. Measure the weight of all sieves (with soil), as well as the bottom pan (with soil). Record your measurements in **Chart B** below.

Chart A: This chart is simply showing you how and where to write your calculations. You do not fill-in any information in this chart.

Sieve #	Opening Diameter (mm)	Weight of Empty Sieve or Pan (g)	Weight of Sieve or Pan + Soil Retained (g)	Soil Retained (g)	Percent Retained
		A	B	W ($W = A - B$)	P ($P = W / Total Weight * 100$)
#6	3.40 mm	weight of empty sieve	weight of sieve and soil	W1	$P1 = W1 / W * 100$
#20	0.86 mm	weight of empty sieve	weight of sieve and soil	W2	$P2 = W2 / W * 100$
#40	0.38 mm	weight of empty sieve	weight of sieve and soil	W3	$P3 = W3 / W * 100$
#100	0.15 mm	weight of empty sieve	weight of sieve and soil	W4	$P4 = W4 / W * 100$
Pan		weight of empty pan	weight of sieve and soil	Wpan	$Ppan = Wpan / W * 100$
Total Weight =				W1+W2+W3 +W4+Wp *should = 100g	

Chart B: This is the chart where you record your answers based on your calculations.

Sieve #	Opening Diameter (mm)	Weight of Empty Sieve or Pan (g)	Weight of Sieve or Pan + Soil Retained (g)	Soil Retained (g)	Percent Retained
		A weight of empty sieve	B weight of sieve and soil	W ($W = A - B$)	P ($P = W / Total Weight * 100$)
#6	3.40 mm				
#20	0.86 mm				
#40	0.38 mm				
#100	0.15 mm				
Pan					
Total Weight =					

Activity #4: NPK and pH

NPK:

Plants require nutrients to grow and thrive. Macronutrients include Nitrogen, Phosphorus, Potassium, Calcium, Magnesium and Sulfur. Micronutrients include Boron, Chlorine, Copper, Iron, Manganese, Molybdenum and Zinc. Plants take in micronutrients in smaller amounts than the macronutrients. Conduct a soil test to determine the amount of nutrients in your soil.

Nitrogen makes up 78% of the Earth's atmosphere, followed by oxygen which constitutes 21%. In the atmosphere, nitrogen exists as a gas, (N₂). In the soil, nitrogen is in constant flux, and it is difficult to discern how much is in the soil at any given time. As (N₂), nitrogen can easily leach out of the soil and is lost to plants. In order for plants to use (N₂), it needs to be converted, or "fixed". Nitrogen fixation is carried out by microbes in the soil, specifically, bacteria. The bacteria combine the nitrogen molecules with oxygen or hydrogen into compounds that plants can absorb, such as ammonium (NH₄⁺), or nitrate (NO₃⁻). Some microbes have developed a symbiotic relationship with plants, including legumes (beans and peas). The bacteria take up residence in the root hairs of these plants and fix the nitrogen in the surrounding soil, which is then directly taken in by these plants. Plants provide the bacteria with exudates in the form of sugars.

Phosphorus (P) occurs naturally in minerals, living organisms and in water. Plants use phosphorus in the form of orthophosphates (H₂PO₄⁻). It is a vital component in plant processes that involve energy transfer. Phosphorus helps to harvest the energy from the sun and convert it into growth and reproduction.

Potassium (K⁺) is associated with the movement of water, nutrients and carbohydrates in plant tissue. Plants sufficient in potassium maintain turgor which reduces water loss and wilting, and increases root growth which leads to more drought resistant plants.

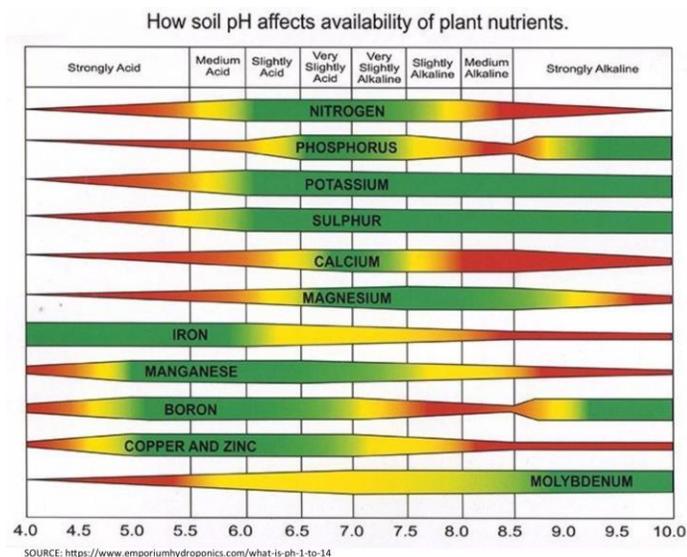

Nutrient	For Plants	For Us
Nitrogen (N)	Leaf, stem, and root growth, green color (chlorophyll)	Proteins and amino acids needed for all our cells
Potassium (K)	Water uptake, improves resistance to pests and disease	Healthy muscles and blood circulation
Calcium (Ca)	Leaf and root growth, cell division, nutrient uptake	Strong teeth and bones
Magnesium (Mg)	Photosynthesis, activates enzymes	Heart and blood vessels
Phosphorus (P)	Flowers, fruits, and seeds.	Helps brain and nerves work
Sulfur (S)	Amino acids and photosynthesis	Amino acids and proteins for growth

pH:

The availability of nutrients is contingent on the soil's pH. What is pH? pH is an abbreviation for "the power of Hydrogen". A pH test measures the concentration of hydrogen ions (H⁺) in the soil solution, which determines the soil's **acidity** and **alkalinity**. On a scale of 1 to 14, the center of the scale, 7, is neutral and is based on the number of hydrogen ions present in pure water. Each step to the left of the 7 shows an increase by 10 times in the number of hydrogen ions present in the soil solution. A pH of 1 would be very acidic – battery acid. Each step to the right shows a decrease in the number of hydrogen ions present in the soil solution. A pH of 14 would be very alkaline or basic – bleach.

If we take an example of water: H₂O, we know that water has 2 Hydrogens for every 1 Oxygen per molecule. A very tiny percentage of those molecules have broken up into hydrogen ions (H⁺) and hydroxide ions (OH⁻). When the hydrogen ions outnumber the hydroxide ions, the solution is acidic. When the hydroxide ions outnumber the hydrogen ions, the solution is alkaline/basic.

Why is it important to know your soil's pH? Soil pH affects the availability of nutrients in your soil for plants. Gardener's typically shoot for a soil pH of 6.5 to 6.8. That's the soil sweet spot. It's where most nutrients are available, and where plants and soil organisms do best. Look at the chart below, notice how nitrogen begins to drop off when pH hits 5.5, and look at the impact on phosphorus when pH is 6. The best way to buffer your soil pH is to add organic matter to the soil.

Results of your NPK Test:

N: _____

P: _____

K: _____

Results of your pH Test:

pH: _____
