TECH LAB

# Does DNA profiling deter criminal behavior?

- Use of DNA databases and similar high-tech tools is expanding around the world
  - Work primarily by increasing the probability of getting caught (instead of punishment)
  - These tools have great potential, but surveillance brings privacy costs
    - Citizens want to know what they're getting in exchange for their privacy
- We consider effects of DNA databases on recidivism in Denmark, using the timing of a massive database expansion as a natural experiment

## **Research Question:**

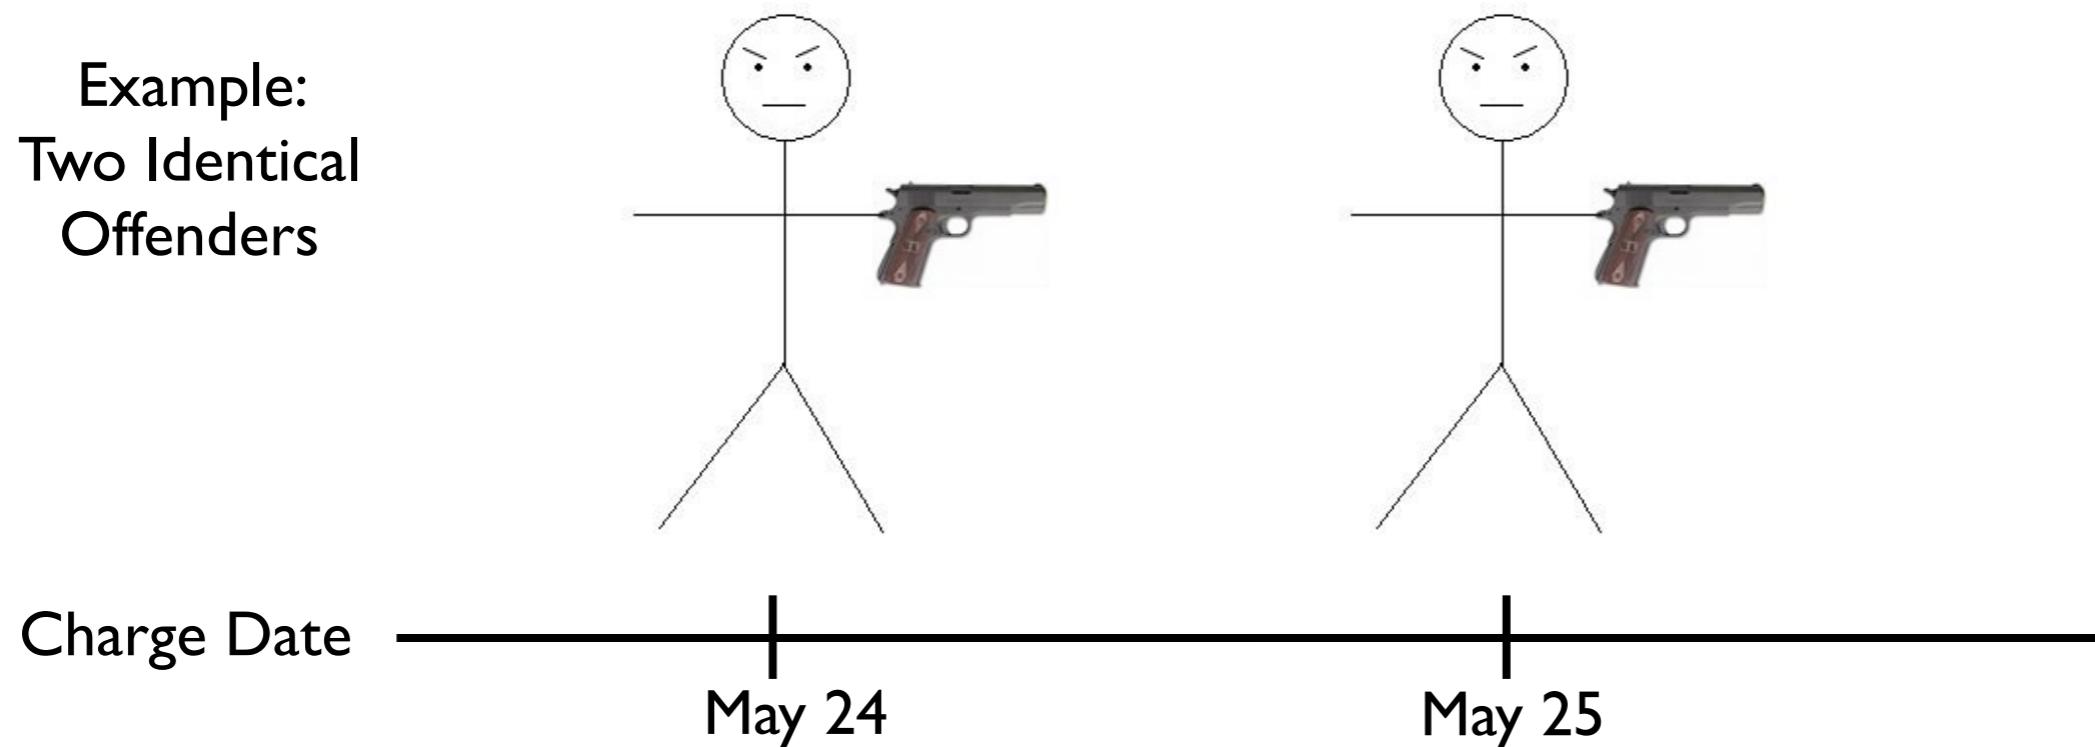

What are the effects of DNA databases on individuals in the database?

# Literature on DNA databases

- There's very little evidence on databases' causal effects on behavior
  - Doleac (2017) found that DNA databases in the U.S. reduced probability of subsequent convictions by 17% for convicted violent felons and 6% for convicted property felons
  - Data were limited and messy — Denmark has much better data
  - Current policy frontier is adding arrestees, not convicts

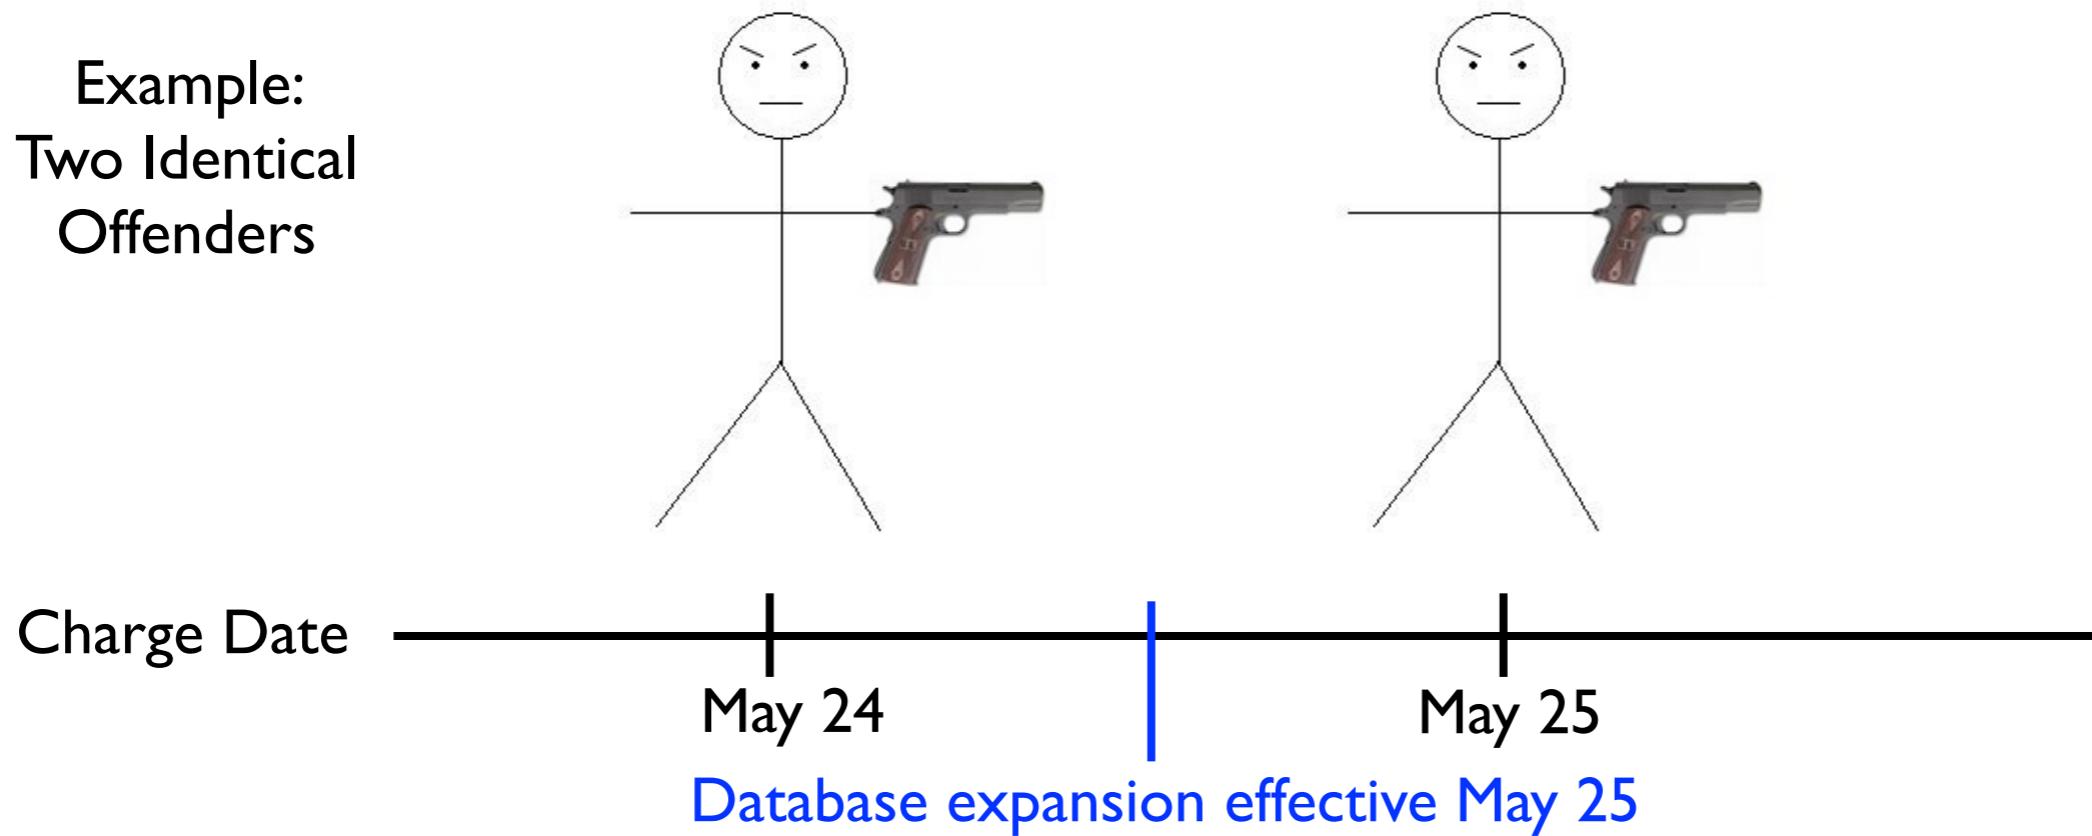

# Using database expansion to measure causal effect on behavior

Example:  
Two Identical  
Offenders

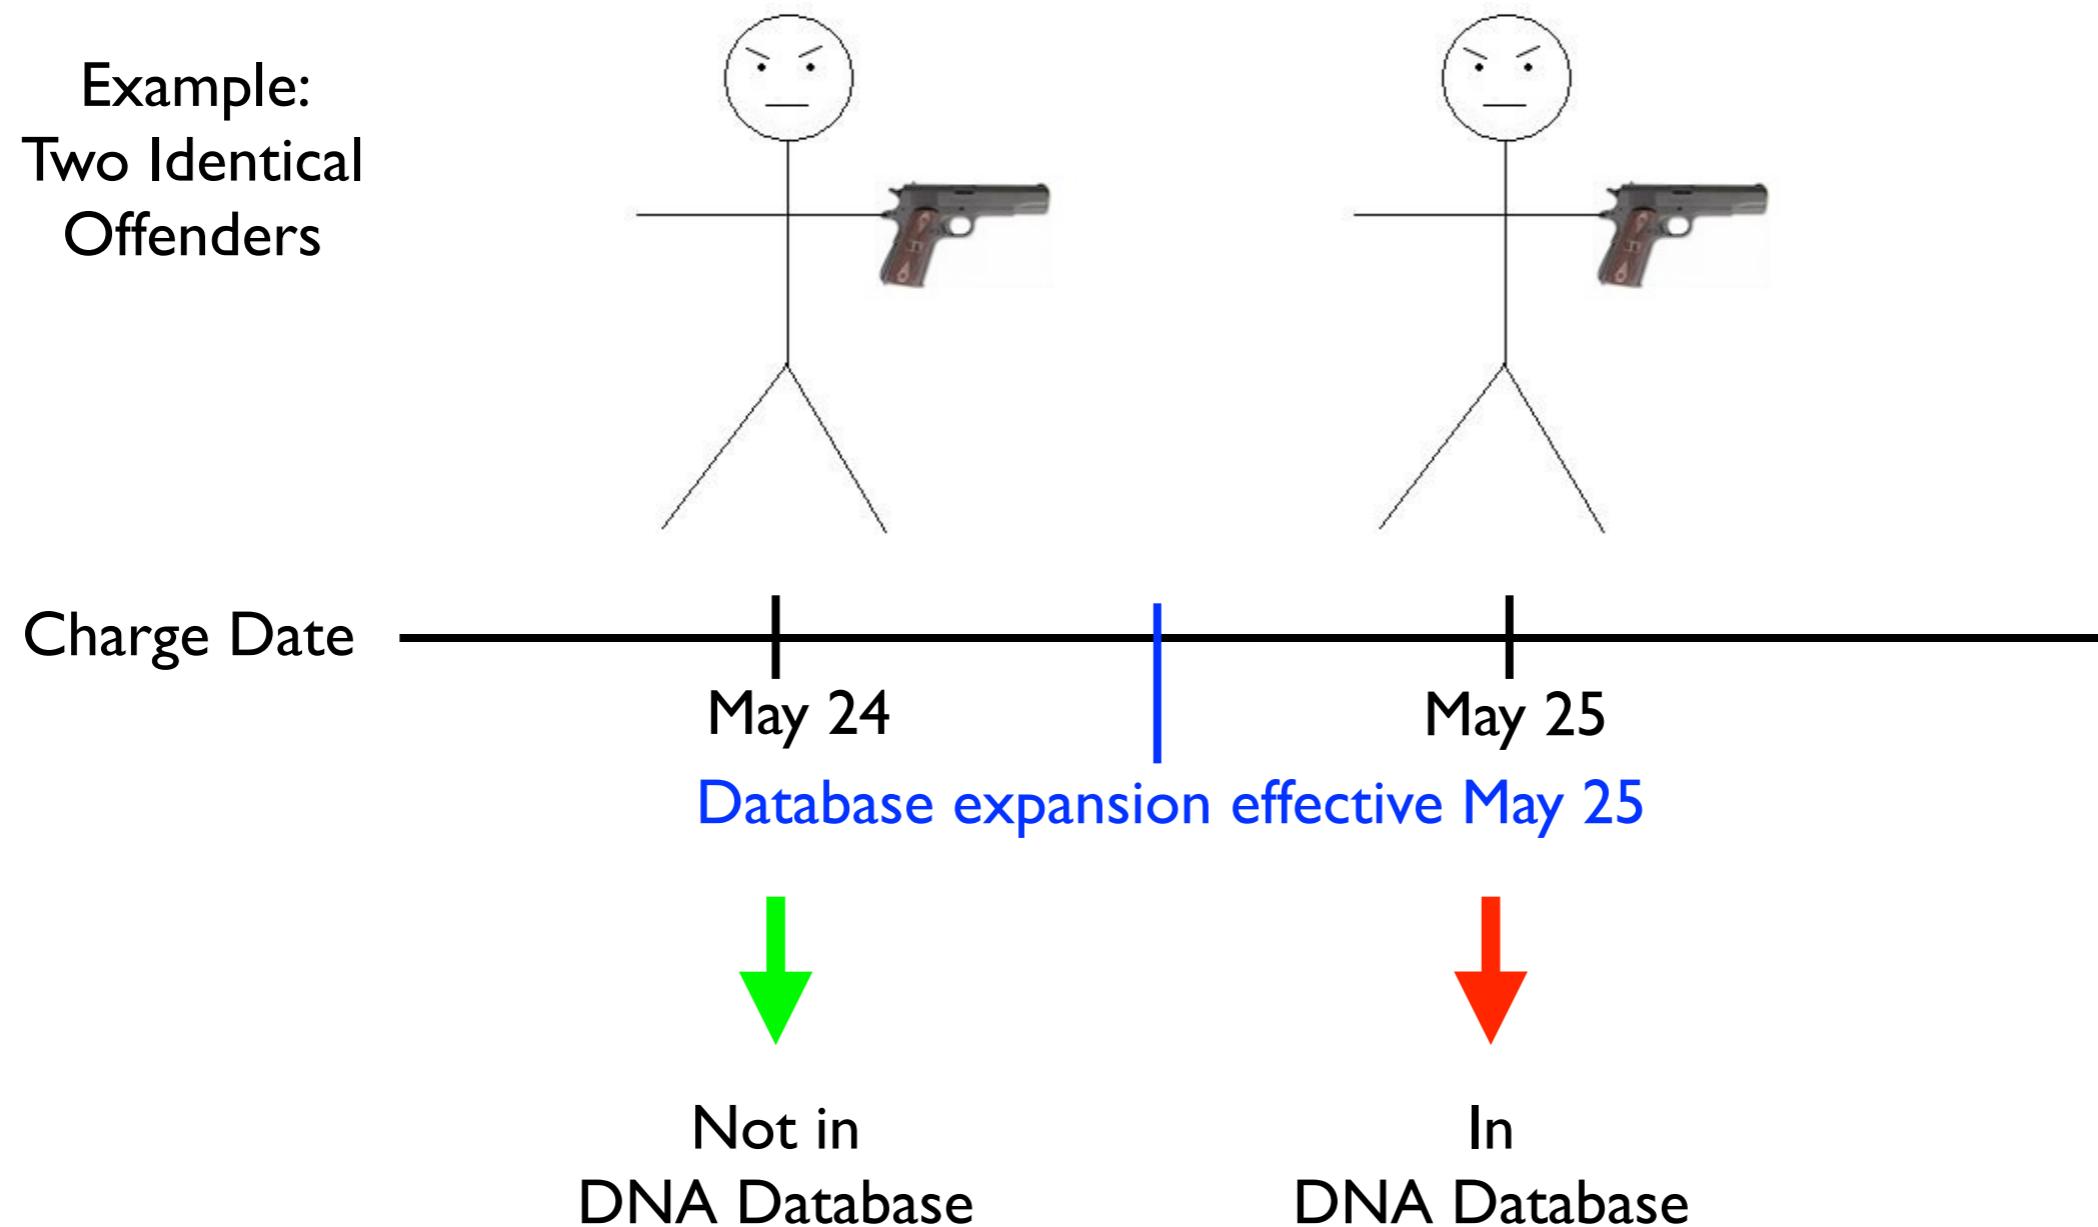

# Using database expansion to measure causal effect on behavior

Example:  
Two Identical  
Offenders

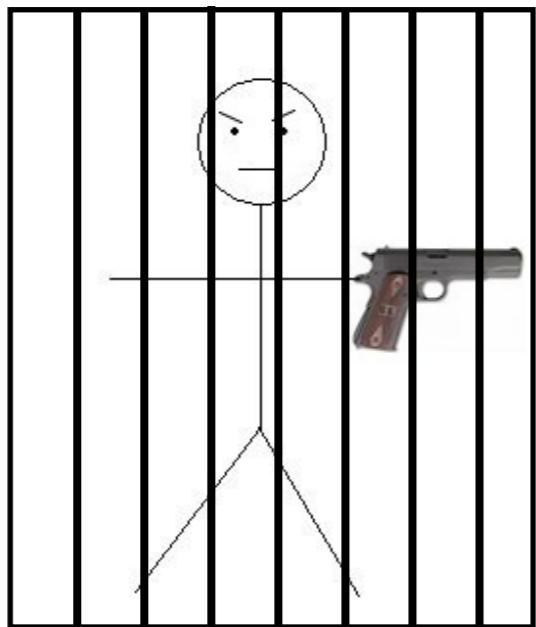

# Using database expansion to measure causal effect on behavior

DNA Database

In  
DNA Database

# What we are measuring

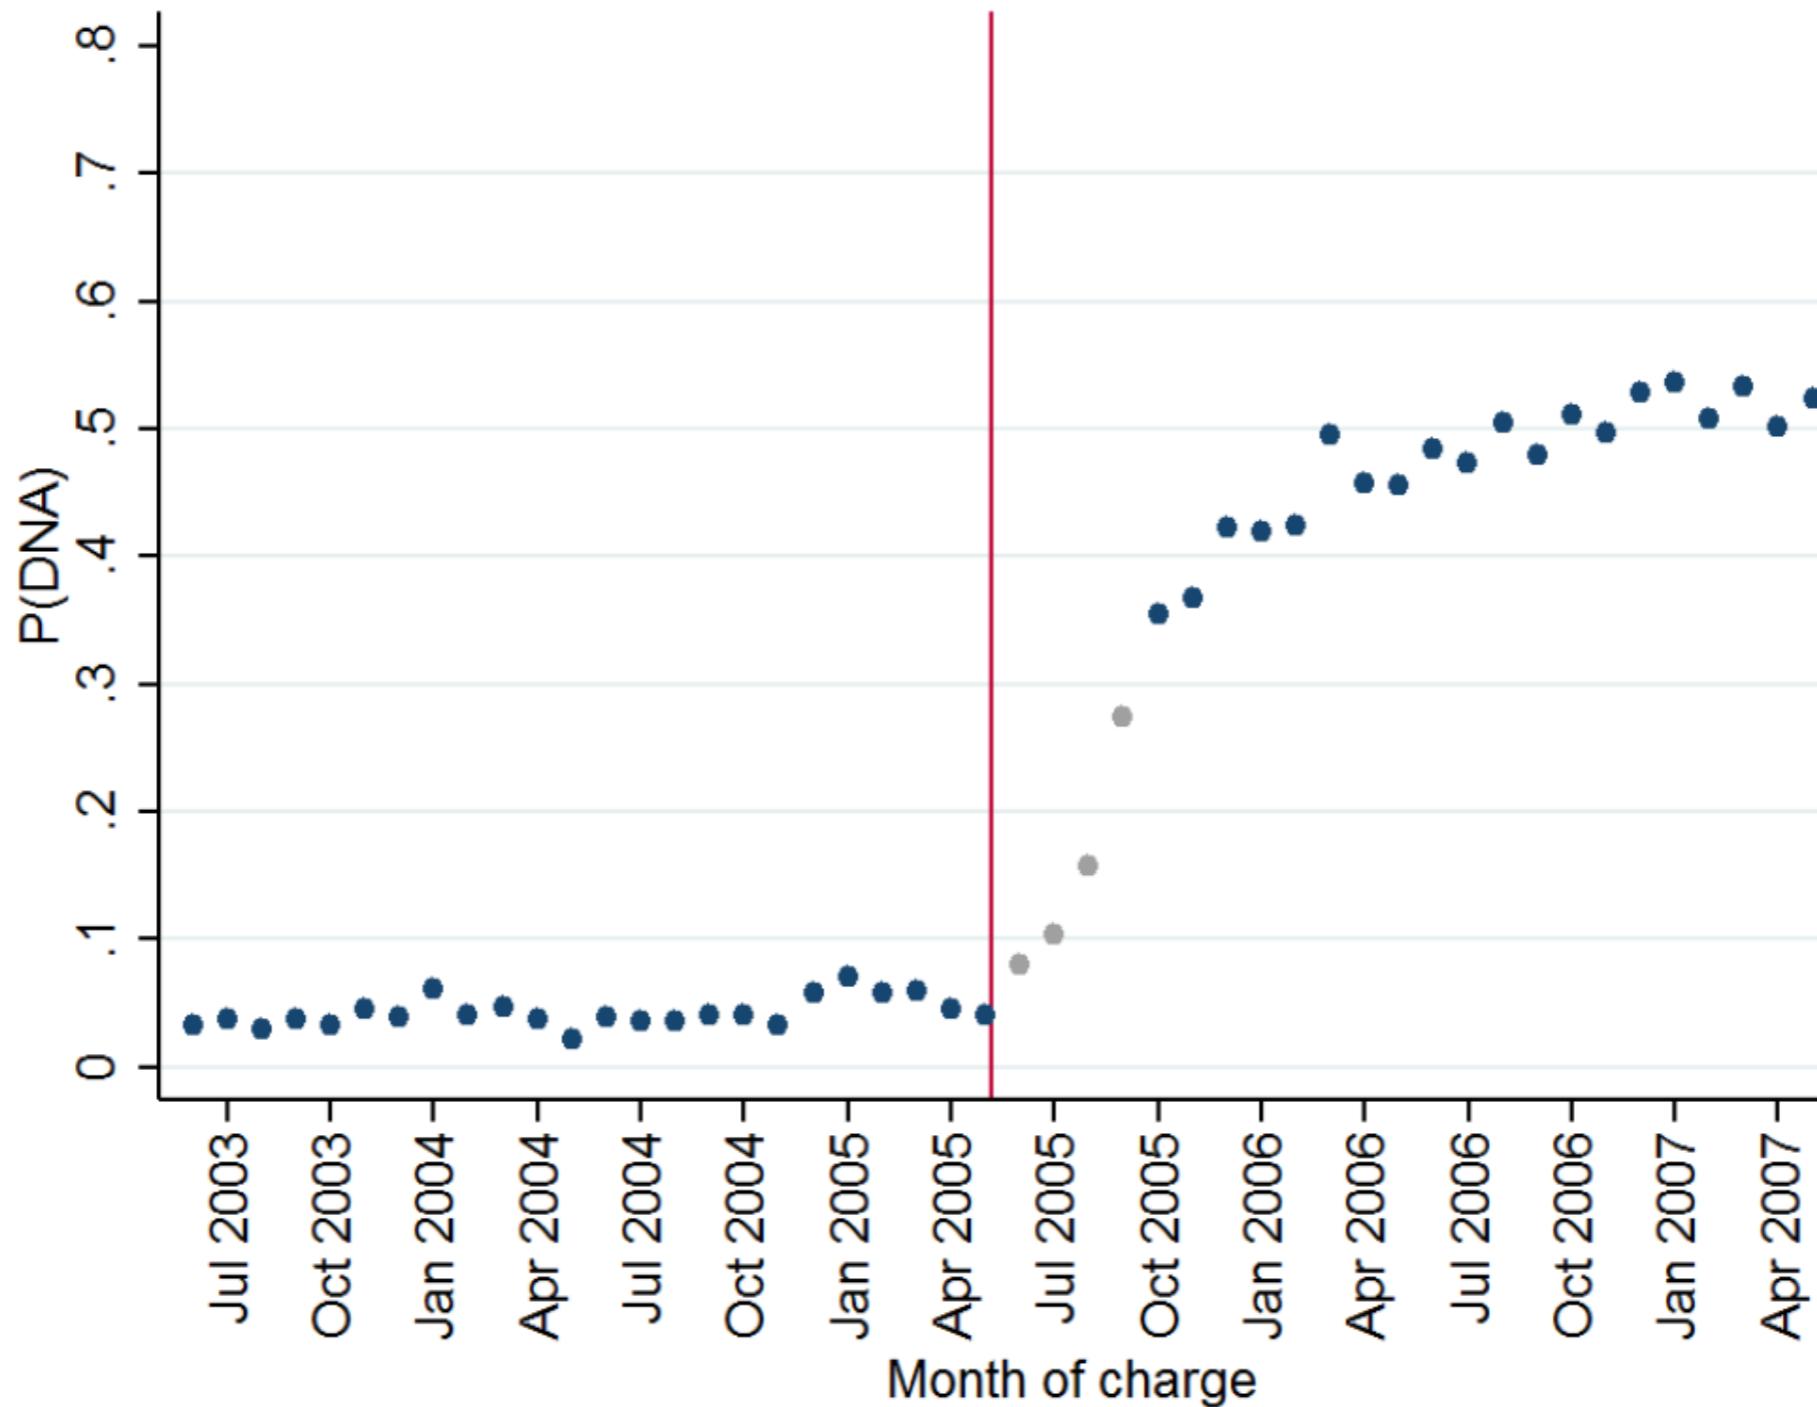

- All other societal changes & changes to the criminal justice system (including a general increase in the collection & use of DNA evidence) will affect those charged before and after the reform
  - Importantly, police can get a warrant to obtain DNA from anyone identified as a suspect in a crime
  - Being added to the DNA database increases the probability that someone is identified as the perpetrator in cases where they would not otherwise be a suspect
    - This is the effect we are identifying

# Background on Denmark's DNA database

- Database first established in 2000, included only those charged with serious violent offenses
  - DNA only collected if necessary for the current investigation
- 2005 expansion added anyone charged with a crime punishable by at least 1.5 years (comparable to all felonies in the U.S.)
  - Removed requirement about relevance to investigation
- Effective May 25, 2005
  - Summer holidays meant police department severely understaffed during June-August, so implementation of the law was slow
  - Probability that a charged individual was added to the database increased from 4% to about 40% by October

# Likelihood of DNA profiling

(a) Likelihood of DNA profiling

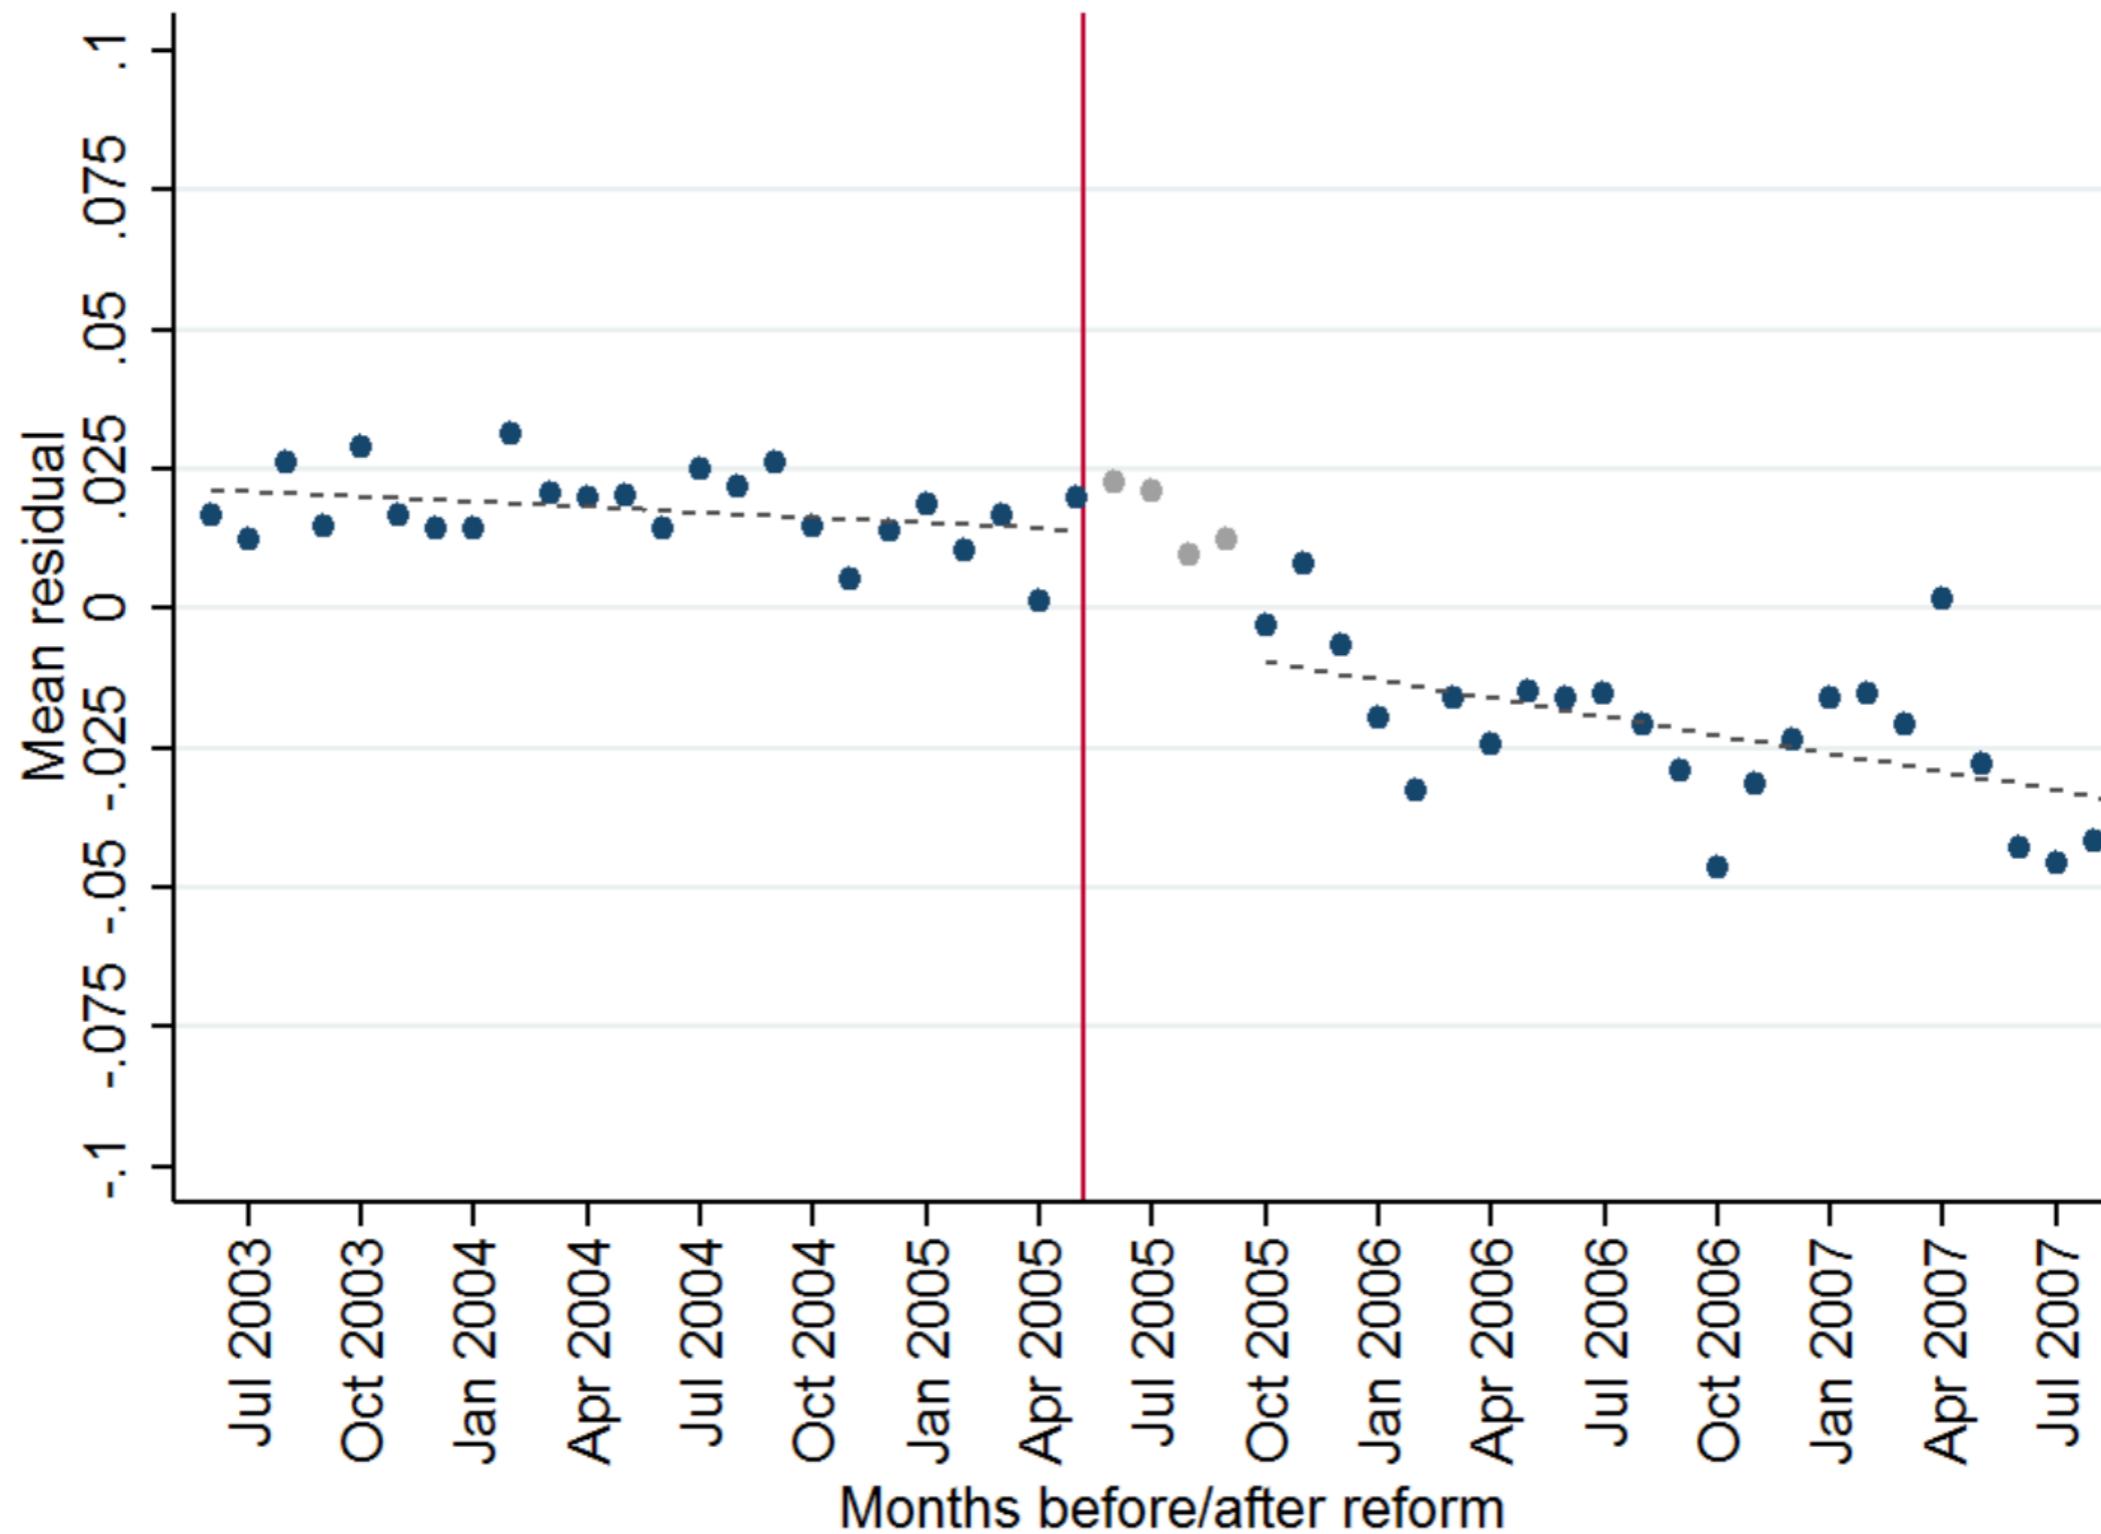

# Data

- Longitudinal criminal history data for the full country
  - Includes when an individual was added to the database, as well as timing and details of future offenses and charges
  - Focus on recidivism over one to three years from the date of the charge
  - Drop individuals who don't reside in Denmark (mostly tourists)
  - Men only, ages 18-30 at time of charge
- These data are linked with information from the Danish register — in particular, marriage, residence, children, employment, education

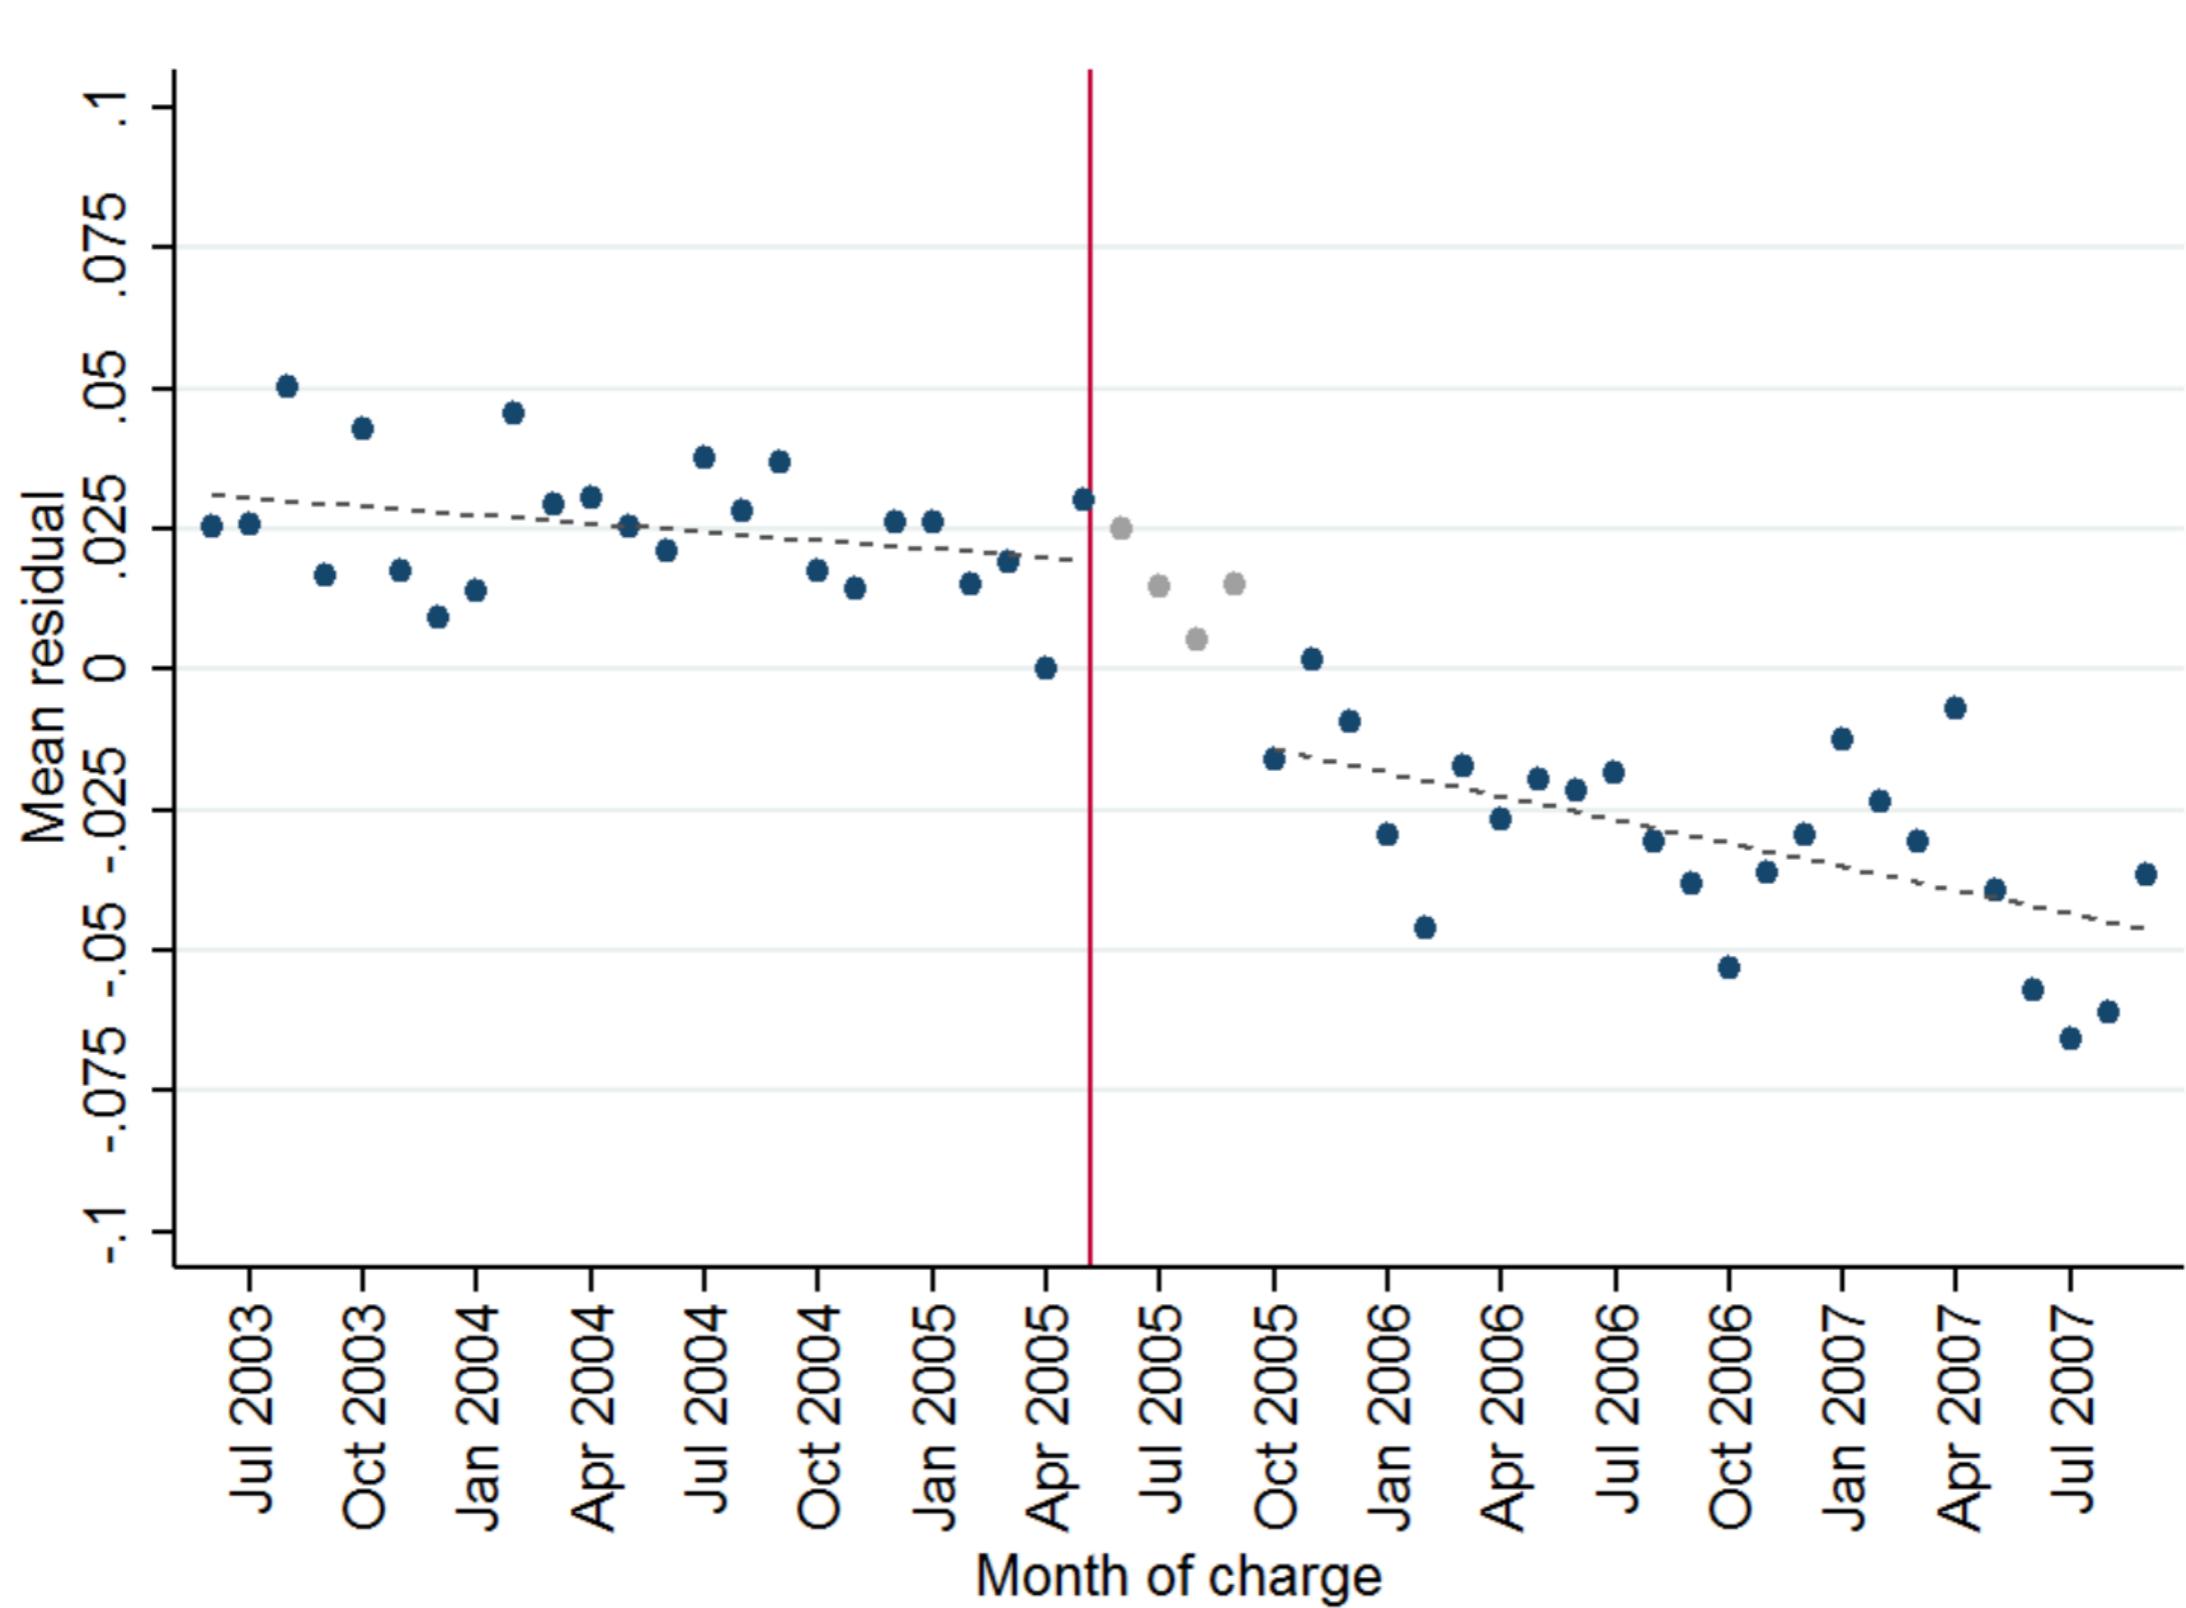

# Empirical strategy

- Use an instrumental variable strategy referred to as a “regression discontinuity”
  - Timing of charge (pre/post expansion) results in a big jump in DNA collection for those charged just after the policy change
    - Does this big jump in DNA collection result in a similar jump or drop in recidivism?
- We drop summer months immediately following expansion date due to slow implementation
  - We worry that those added to the database during the implementation period are a selected sample, could bias results
  - The results are very similar if we include these summer months

# Probability of new conviction within one year falls 42%

# Number of new convictions within one year falls 49%

# Digging into what is driving these effects

## **Which types of offenders are most affected?**

- By initial charge type:
  - Property: 36% decline in year 1,  $p < 0.10$
  - Violent: 48% decline in year 1,  $p < 0.01$
- By first-time vs. repeat offender status:
  - First-time: 83% decline in year 1,  $p < 0.10$
  - Repeat: 38% decline in year 1,  $p < 0.01$
- By age:
  - Age 18-23: 52% decline in year 1,  $p < 0.001$
  - Age 24-30: 2% decline in year 1, not significant
- By whether they had children:
  - Had kids: 55% decline in year 1, not significant
  - No kids: 41% decline in year 1,  $p < 0.01$

## **Which types of crimes are prevented?**

- By subsequent charge type:
  - Property: 42% decline in year 1,  $p < 0.05$
  - Violent: 60% decline in year 1,  $p < 0.05$

# Discussion

- Adding someone *charged* with a felony to Denmark's DNA database reduces probability of a subsequent conviction by 42% during the first year after the initial charge ( $p<0.001$ )
  - Effects persist for at least 3 years
  - Effects are largest for younger offenders (ages 18-23)
  - Deterrent effects apparent for property and violent offenders, and reduce both types of crime going forward

Thank you!
