DON’T LET YOUR HEATING PUMPS WAKE UP UNPREPARED

Summer may have come to an end, but for many commercial and industrial sites, the heating system is about to get busy again.

If your heating pumps have been sitting largely idle for several months, now is the time to give them some attention, before the first cold snap puts them under pressure.

A pump that has been left without regular attention can develop faults, leaks, electrical issues or other problems that may only become apparent when the system is needed most. Regular servicing can help identify deterioration early, reduce unexpected downtime and keep equipment operating efficiently.

🔧 What should a pre-winter pump service include?

A professional inspection can include:

✅ Checking the pump for damage, leaks and unusual vibration
✅ Inspecting electrical connections and control panels
✅ Taking electrical current readings
✅ Checking controls and warning systems
✅ Running and testing the pump and associated controls
✅ Identifying wear, deterioration or potential faults
✅ Providing a service report and recommendations for any remedial work required

❄️ Don’t wait for the first breakdown

The worst time to discover a problem with your heating pumps is when the building needs heating and your maintenance team is already dealing with winter pressures.

A little preventative maintenance now could help avoid an inconvenient and potentially costly emergency call-out later.

At Cougar Pumps, we service pumps and pumping systems for commercial and industrial customers, including heating pumps, and can provide both one-off servicing and planned preventative maintenance programmes.
